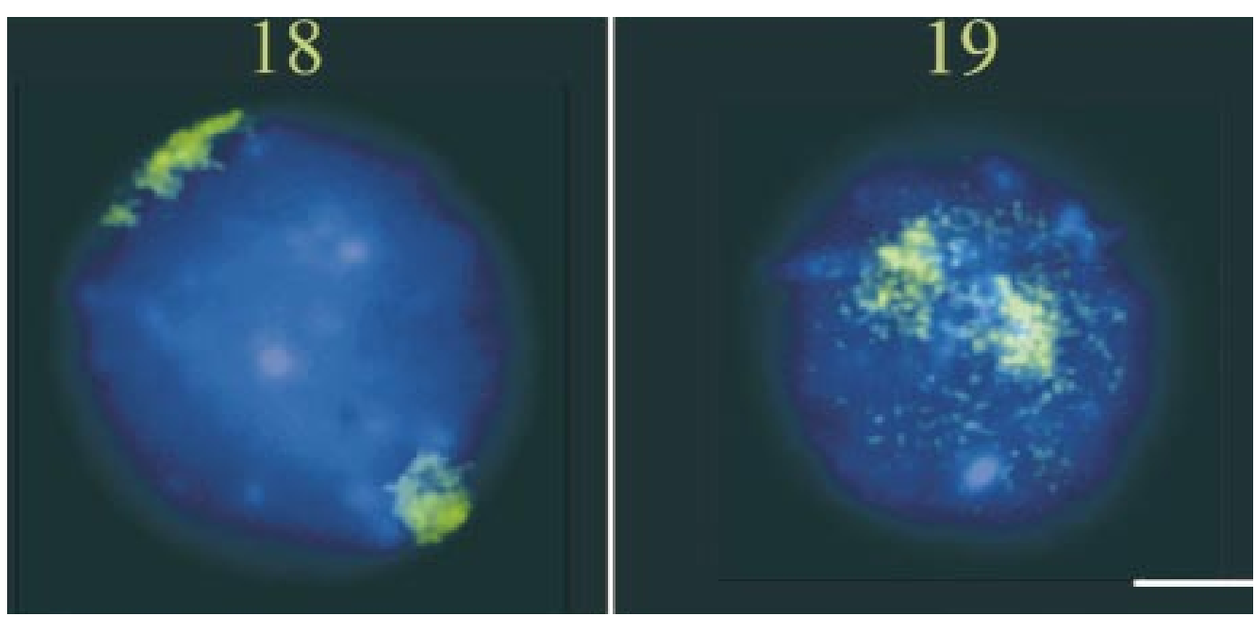
The Journal of Cell Biology, Volume 145, Number 6, June 14, 1999 1119–1131

Abstract. Using fluorescence in situ hybridization we show striking differences in nuclear position, chromosome morphology, and interactions with nuclear substructure for human chromosomes 18 and 19. Human chromosome 19 is shown to adopt a more internal position in the nucleus than chromosome 18 and to be more extensively associated with the nuclear matrix.

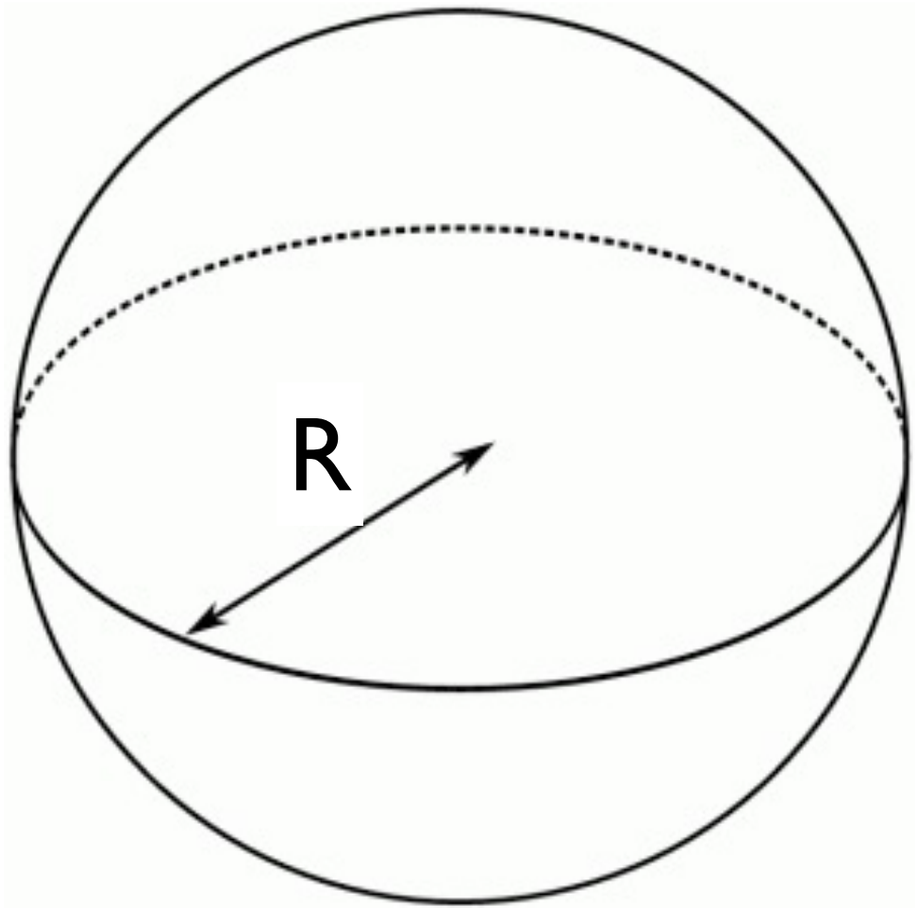
Chromosome 19:
62.03 genes/Mb and
60 Mb size

Chromosome18:
18.64 genes/Mb and
78 Mb size

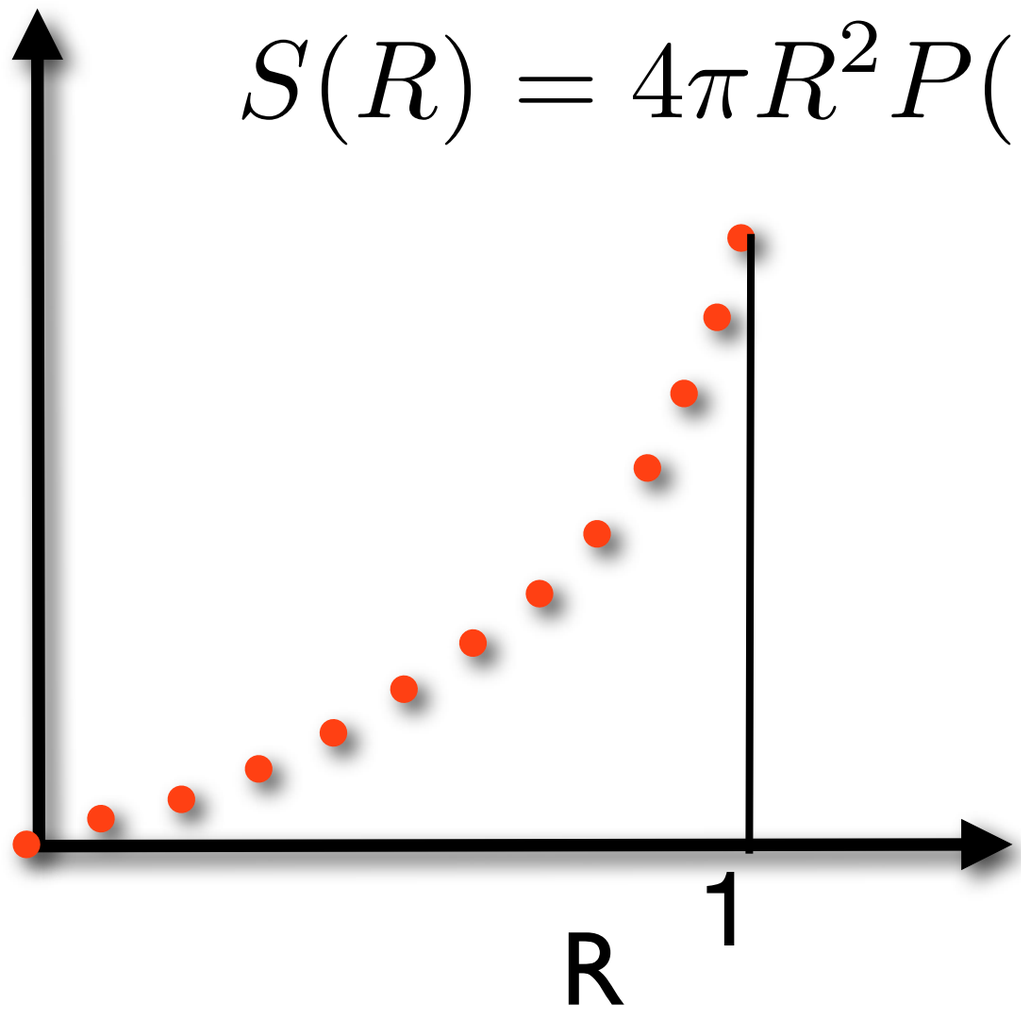


Radial chromosome positioning dependent on gene density?

Radial symmetry



$$S(R) = 4\pi R^2 P(|\vec{R}|)$$



If each chromosome is distributed uniformly throughout the nucleus, then S(R) quadratic, maximum at nuclear envelope

Good diagnostic for non-random placement

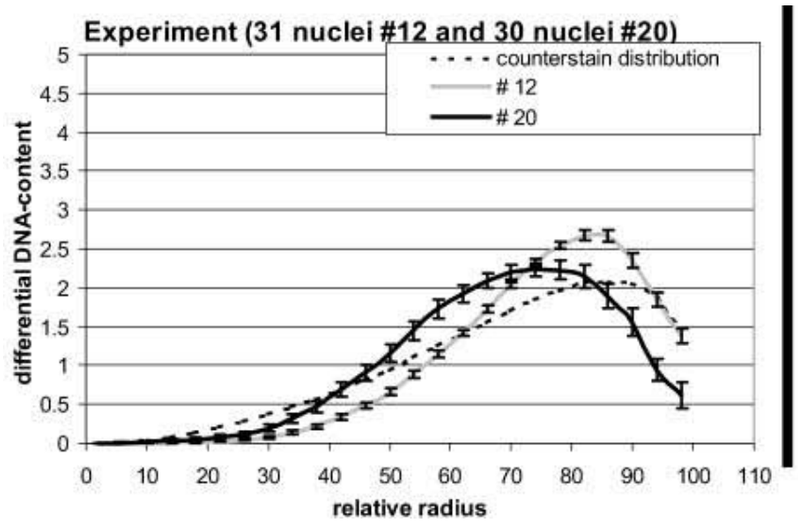
Cremer et al, Chrom. Res. 2001 Weierich et al Chrom Res. 2003, Kreth et al Biophys J 2005

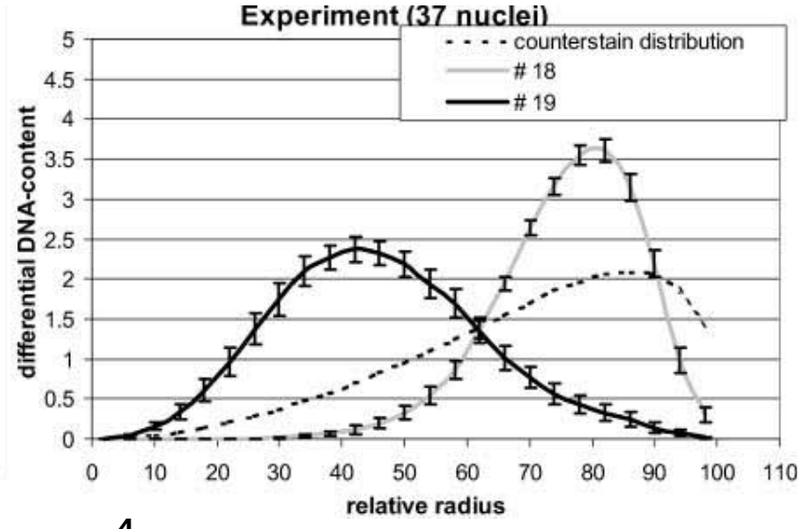
Chromosome 12:
30.92 genes/Mb
and 134 Mb size,

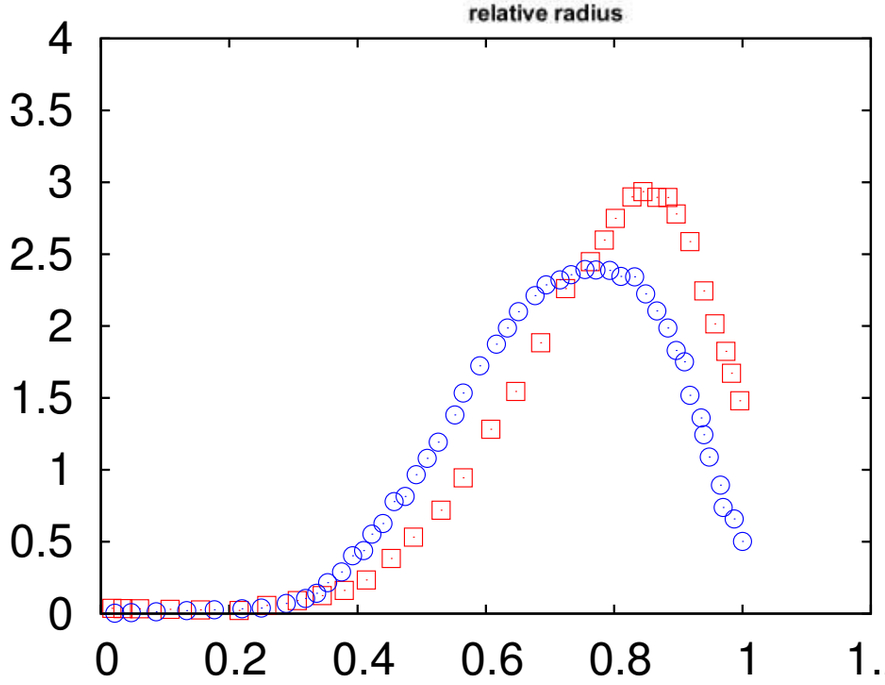
Chromosome 20:
29.71 genes/Mb
and 63 Mb size)

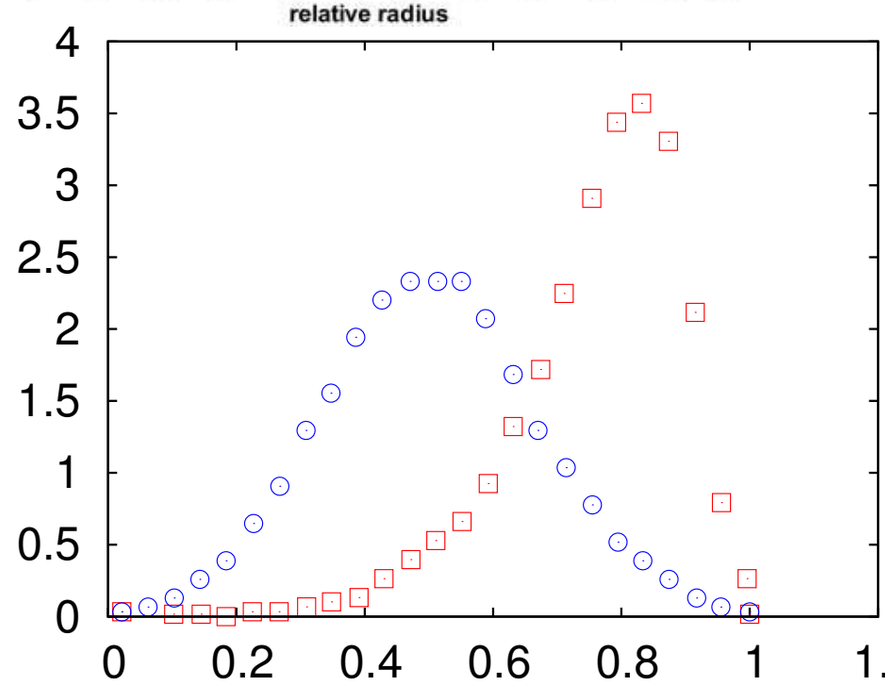
Chromosome 19:
62.03 genes/Mb
and 60 Mb size

Chromosome 18:
(red) 18.64 genes/
Mb and 78 Mb size





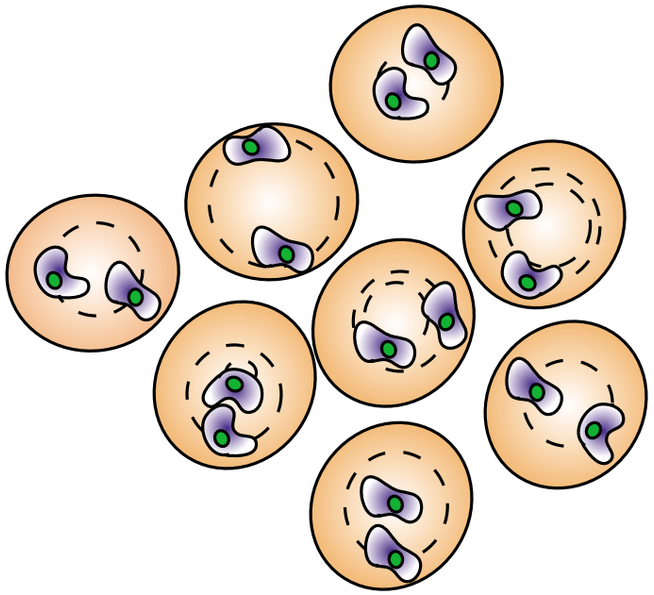




Chromosomes 12 and 20 have different sizes but the same gene density

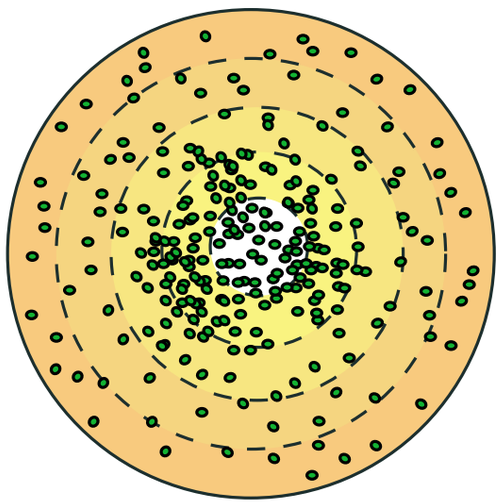
Chromosomes 18 and 19 have roughly the same size but different gene densities

Given that chromosomes are (in many but not all cases) radially ordered by gene density, how do we understand this specific 'positioning rule'?

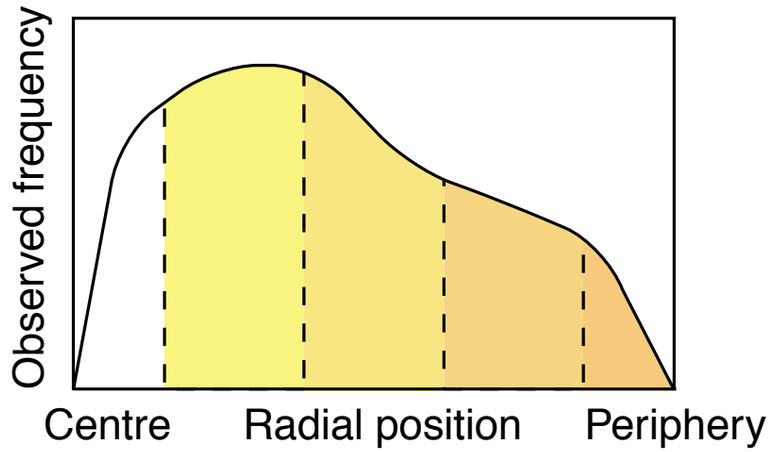


Experimental observation

Graphical representation



Statistical representation

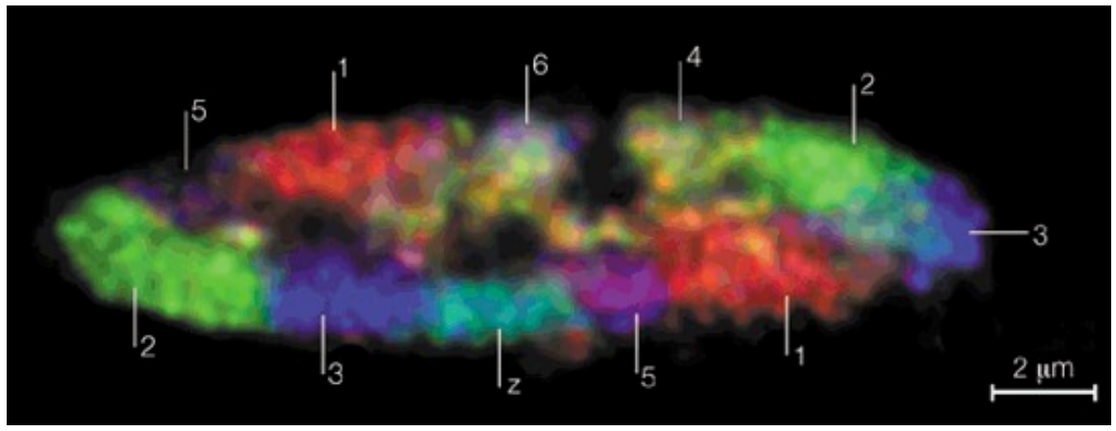


TRENDS in Cell Biology

Parada, Roix, Misteli, Trends in Cell Biology 2003

Hypothesize:

Non-equilibrium mechanical activity (transcription and chromatin remodeling machinery), inhomogeneous across gene-rich and gene-poor regions gives gene-density-based radial segregation



T.Cremer and C. Cremer, Nature Reviews Genetics vol. 2, no. 4, pp. 292-301 (April, 2001)

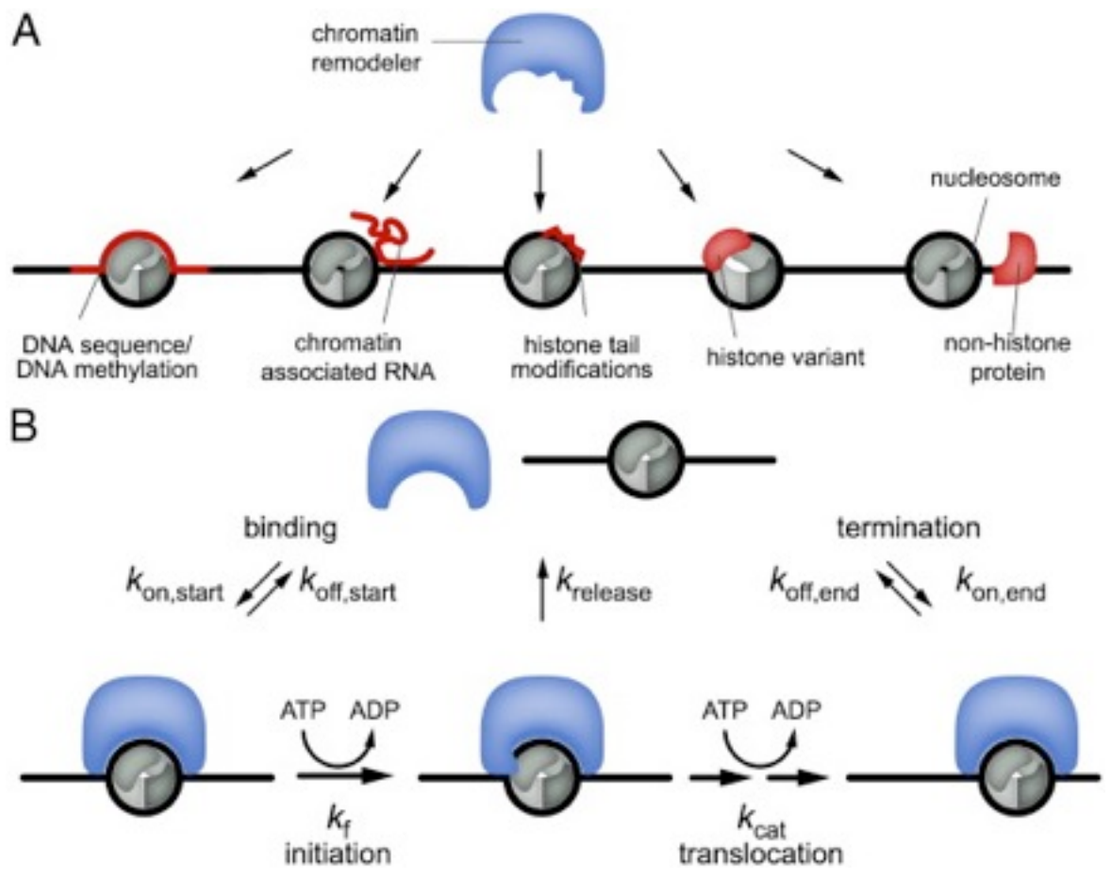
No self-propulsion - unlike in all active matter models studied so far - but inhomogeneous activity, confinement and polymer character all important

Chromosome territories a natural consequence of compact chromosome configurations and activity

Groups of ATPases classified into the Snf2, ISWI, Mi-2, Chd1, Ino80, ERCC6, ALC1, CHD7, Swr1, RAD54, and Lsh subfamilies

Chromatin Remodelers

ATP-driven molecular machines change chromatin structure, translocate nucleosomes, evict nucleosomes, change nucleosomal histone composition, involved in transcription. Work in concert through remodeler-specific interactions. Highly dynamic. Present at large density



Erdel et al, BBA (2011)

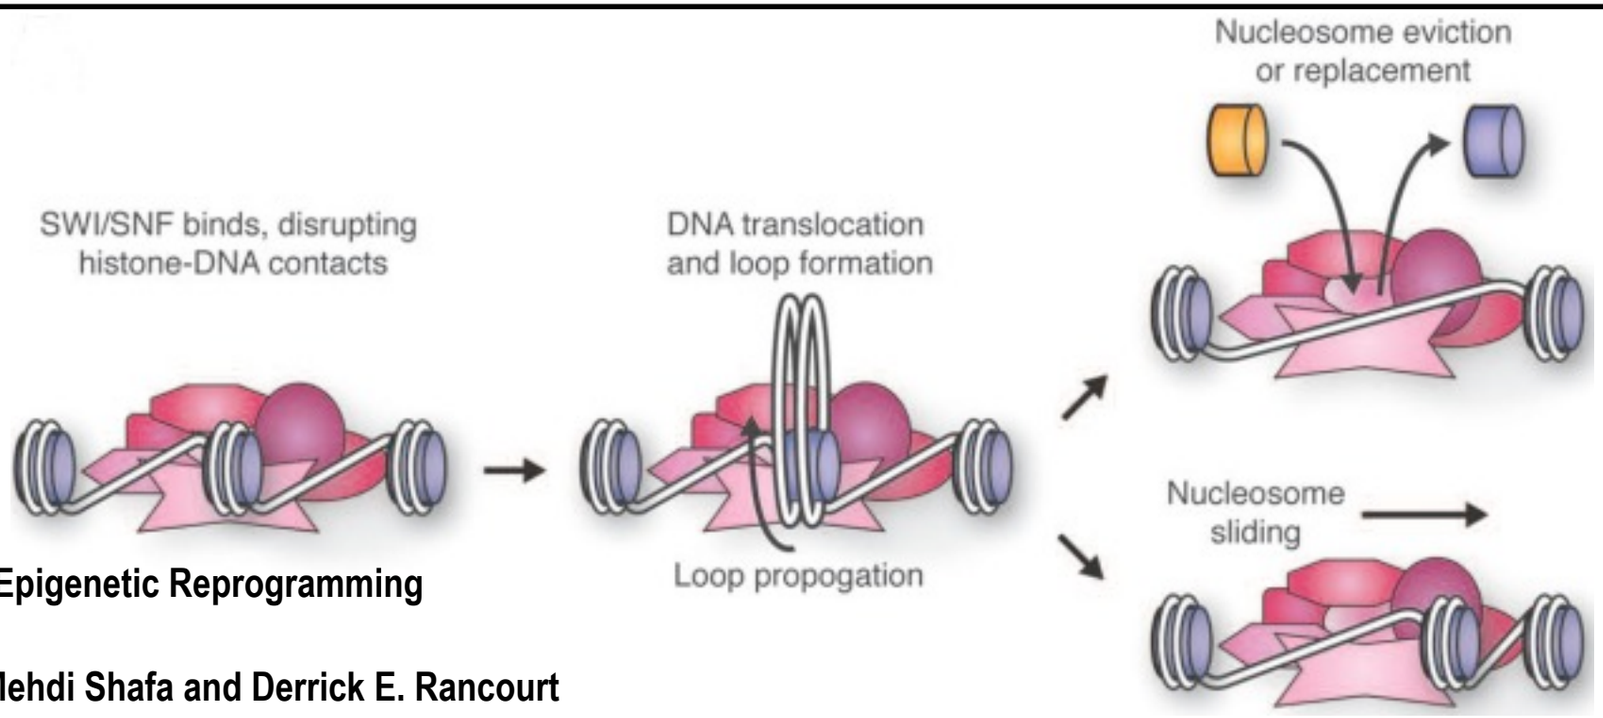
‘Mechanical’ effects of active chromatin remodelers?



Stem Cells and Epigenetic Reprogramming

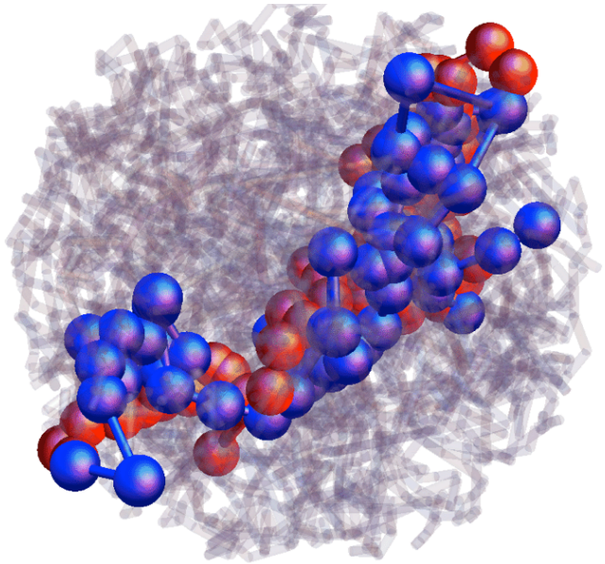
By Perla Cota, Mehdi Shafa and Derrick E. Rancourt

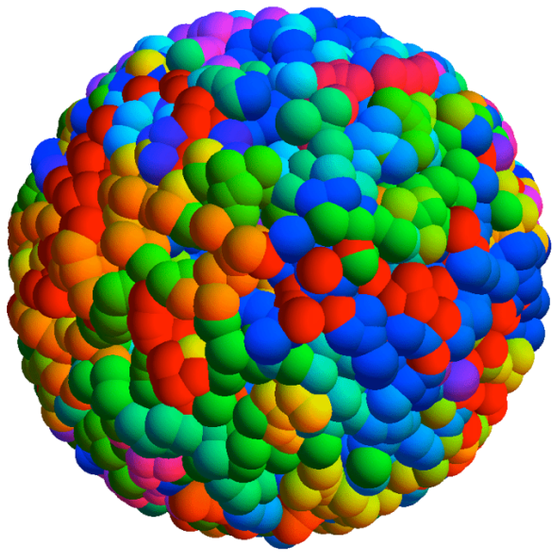
in "Pluripotent Stem Cells", ed. Deepa Bhartiya and Nibedita Lenka, Intech (2013)

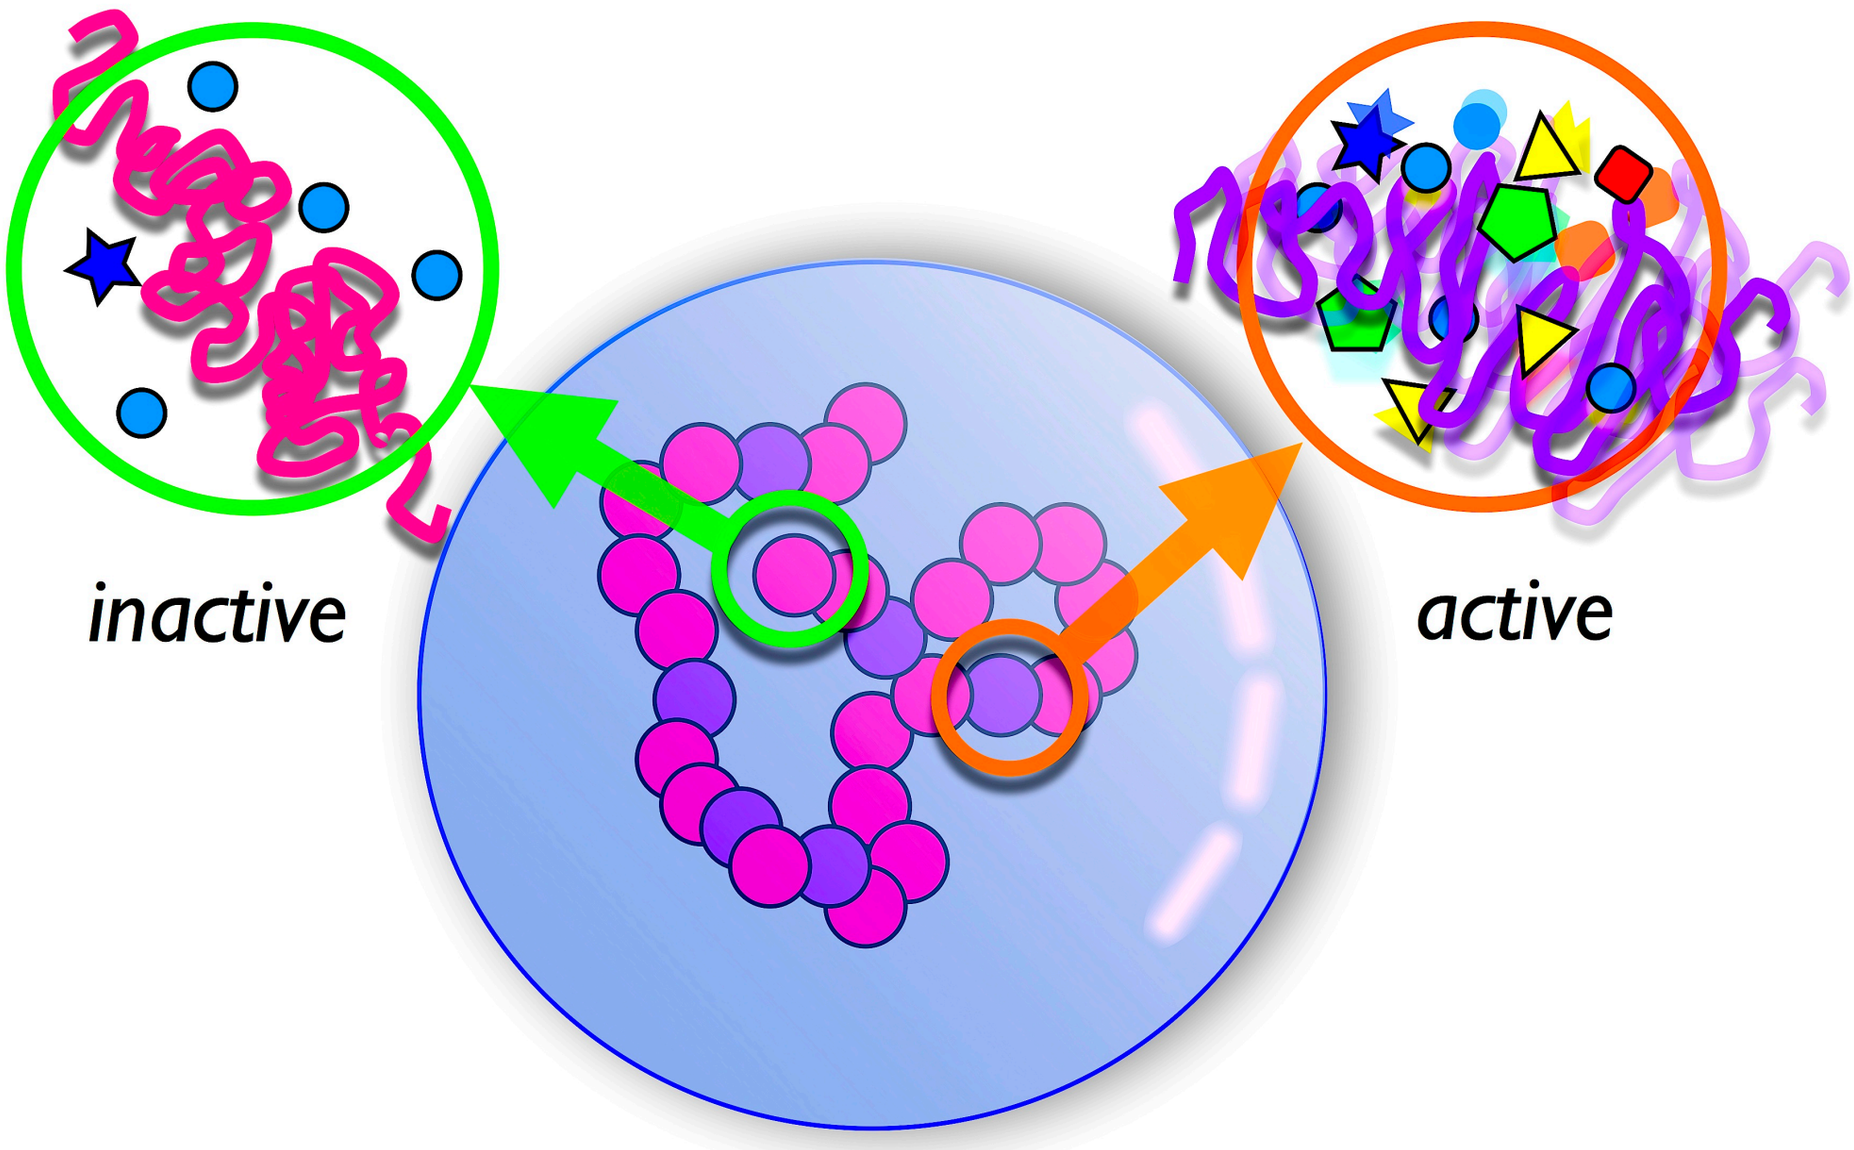
1. Effective local ‘active temperature’ T_{act}, associated with gene density. More transcription implies more ATP-consuming activity from remodeling/transcription-coupled enzymes

2. Coarse-grain to athermal noise acting on, 1Mb scale monomers (Known to be appropriate to functional units of chromosome territories)

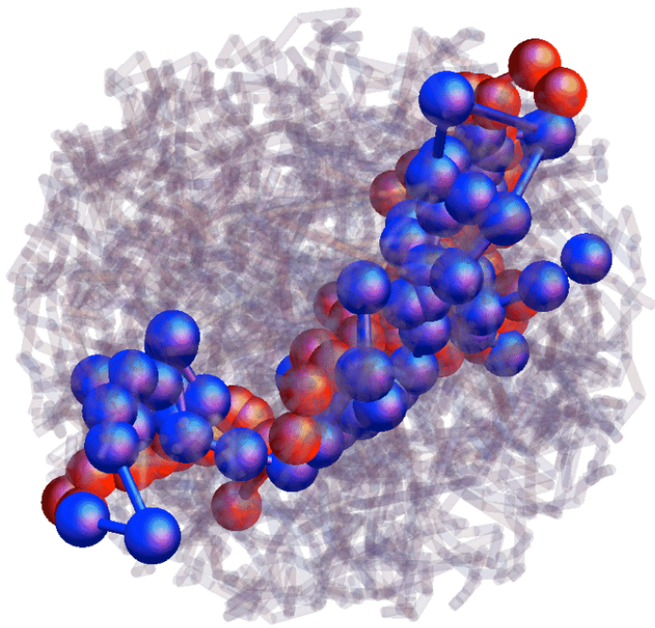
3. Estimate scales of active temperature (barriers to nucleosome motion, etc): $T_{act} = 20 T_{therm}$

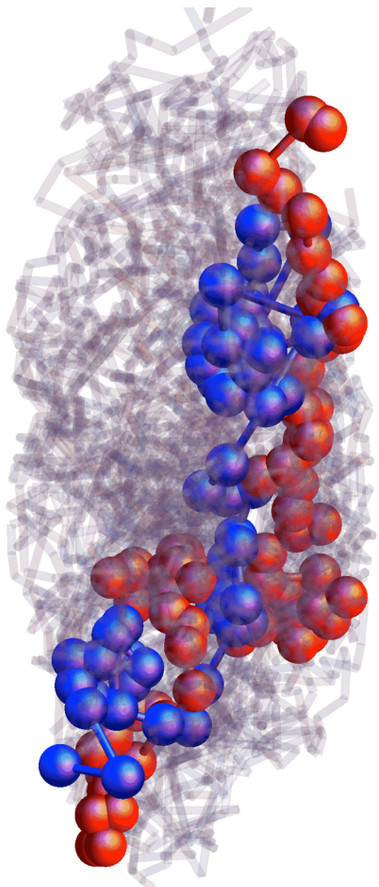


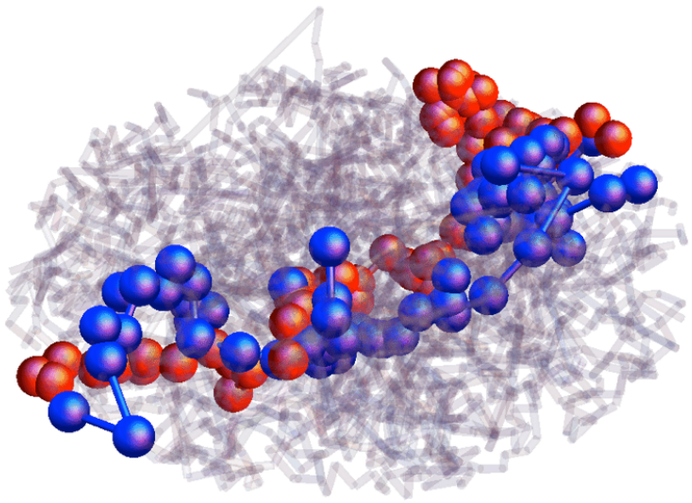




inactive
active







Simulations using the SCD model (spherical chromatin domain)

$$\zeta \frac{d\mathbf{r}_i}{dt} = \mathbf{F}_i + \eta_i$$

$$\langle \eta_i^\alpha(t)\eta_j^\alpha(t')\rangle = 2k_B T_i \zeta \delta_{ij}\delta(t-t').$$

Brownian dynamics, 3-d: 6098 monomers

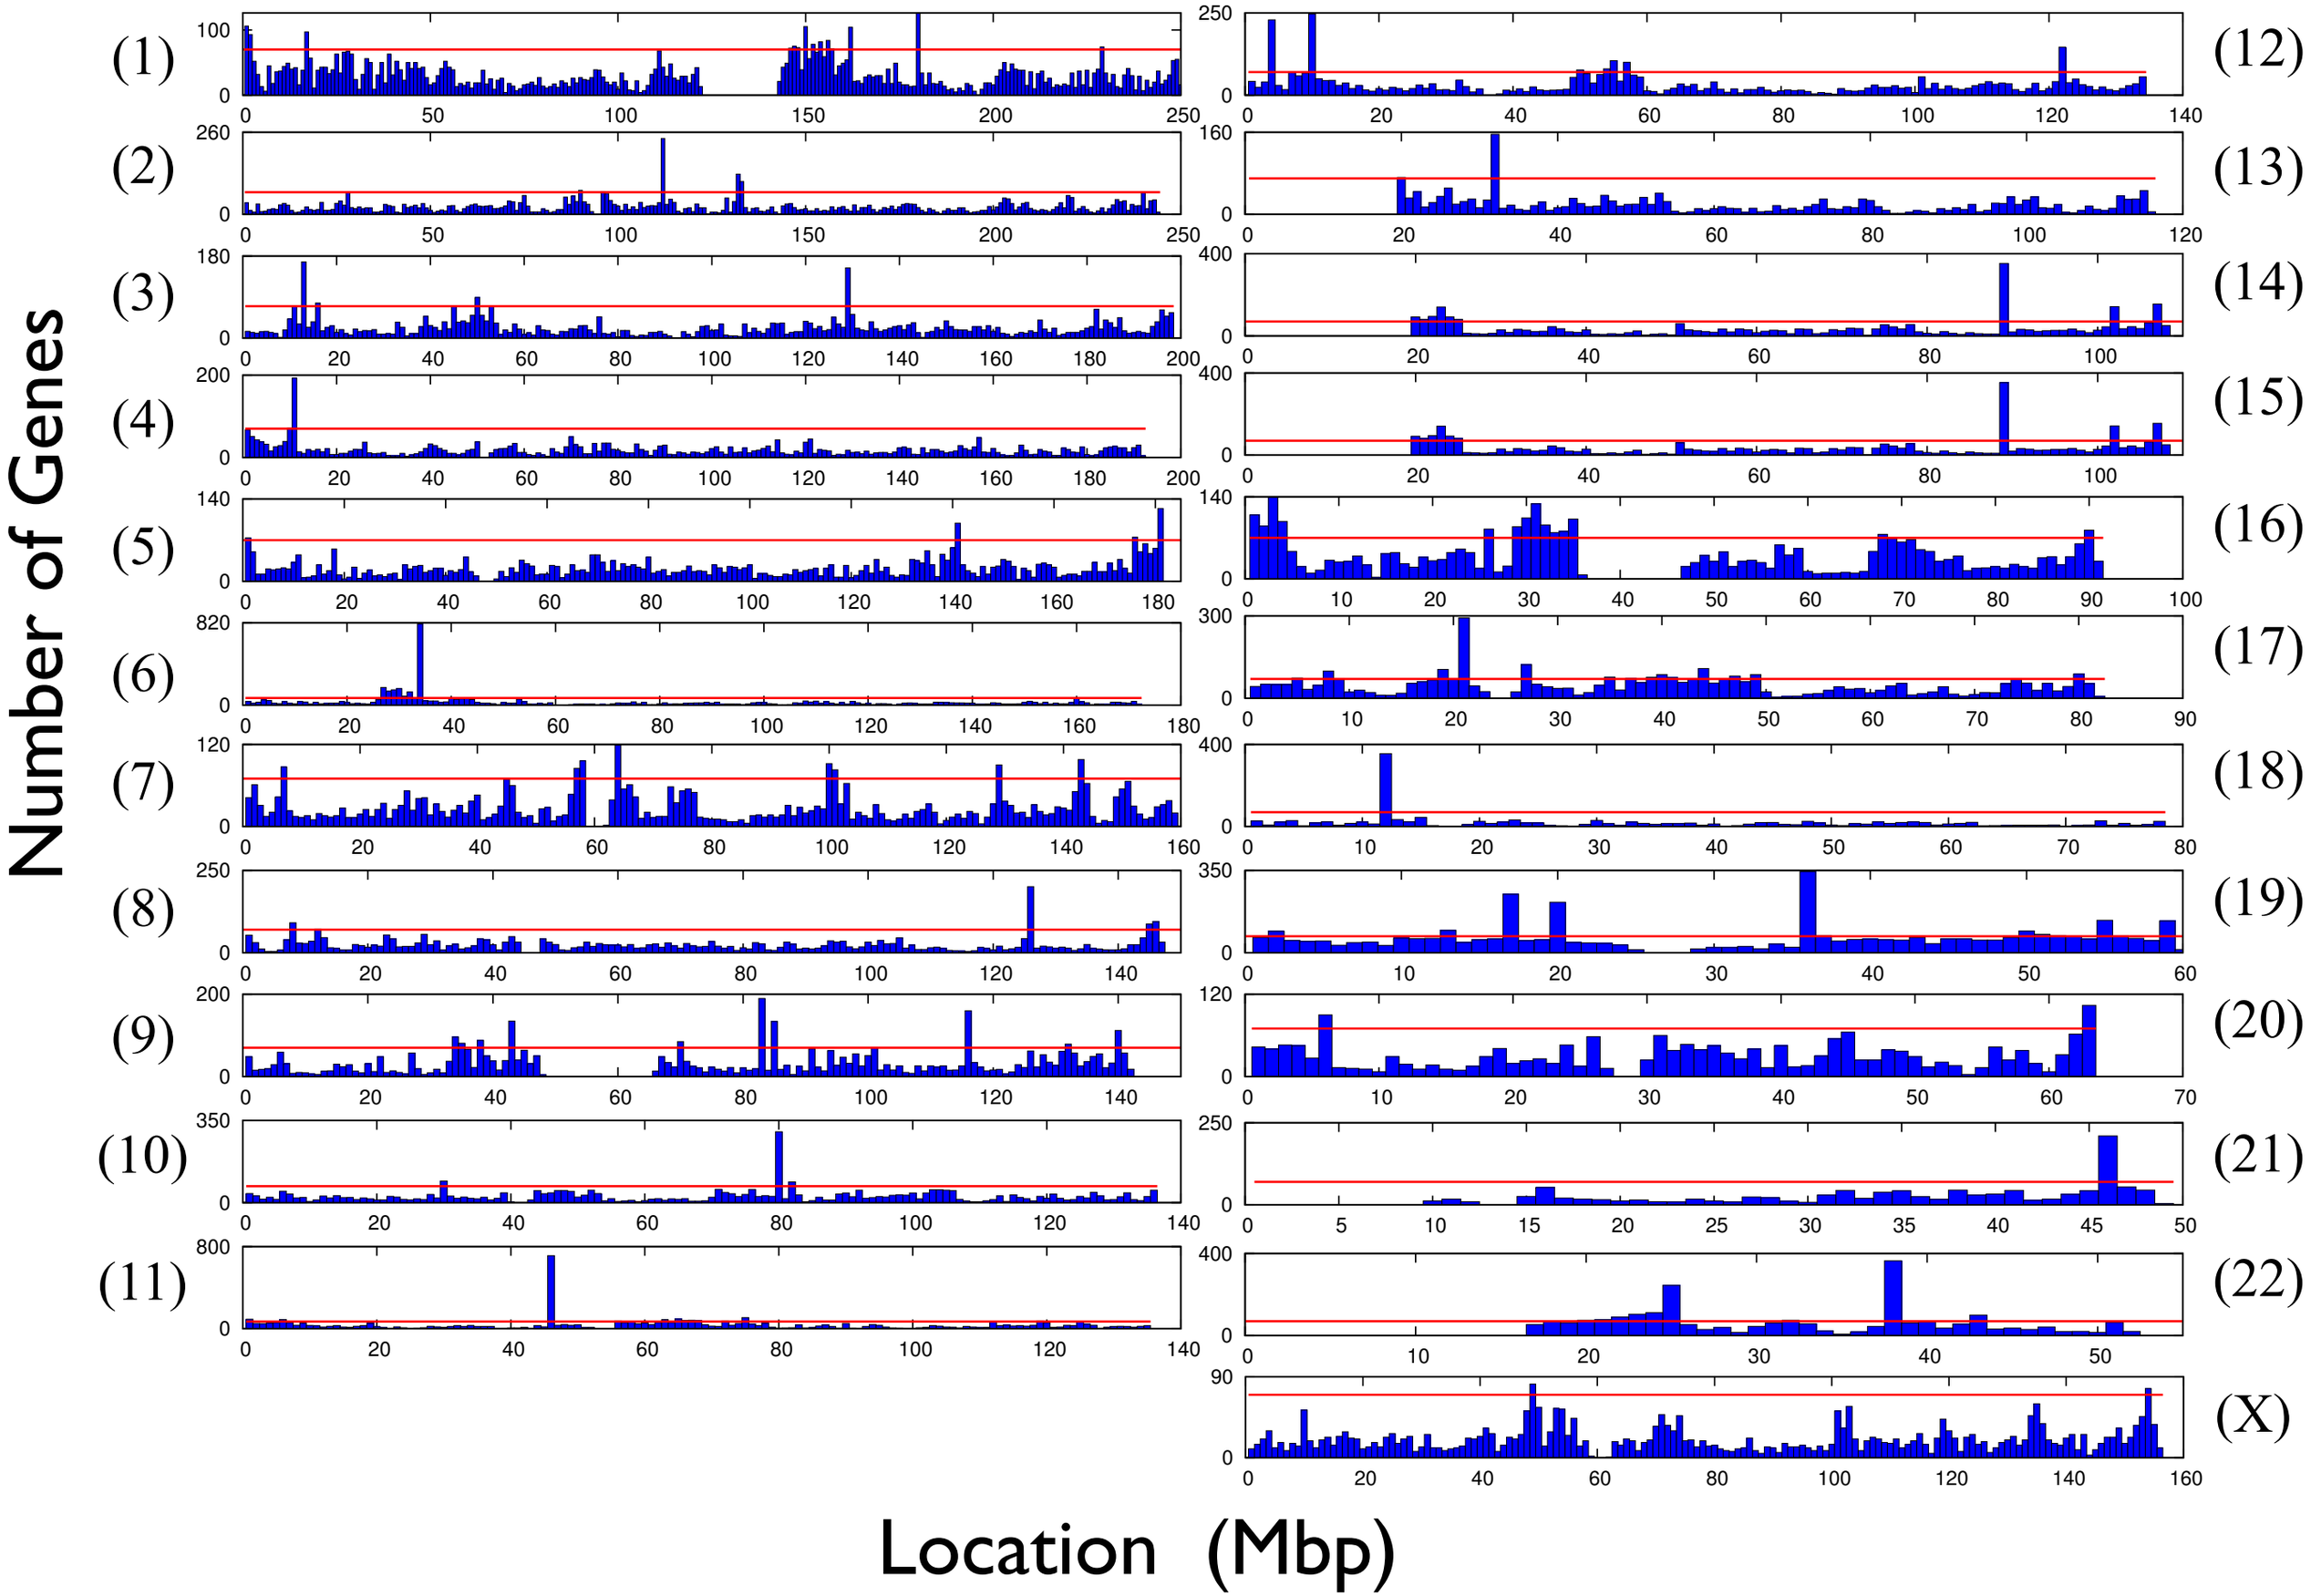
Different effective temperature for each monomer

Assign this depending on gene density (very nonlinearly)

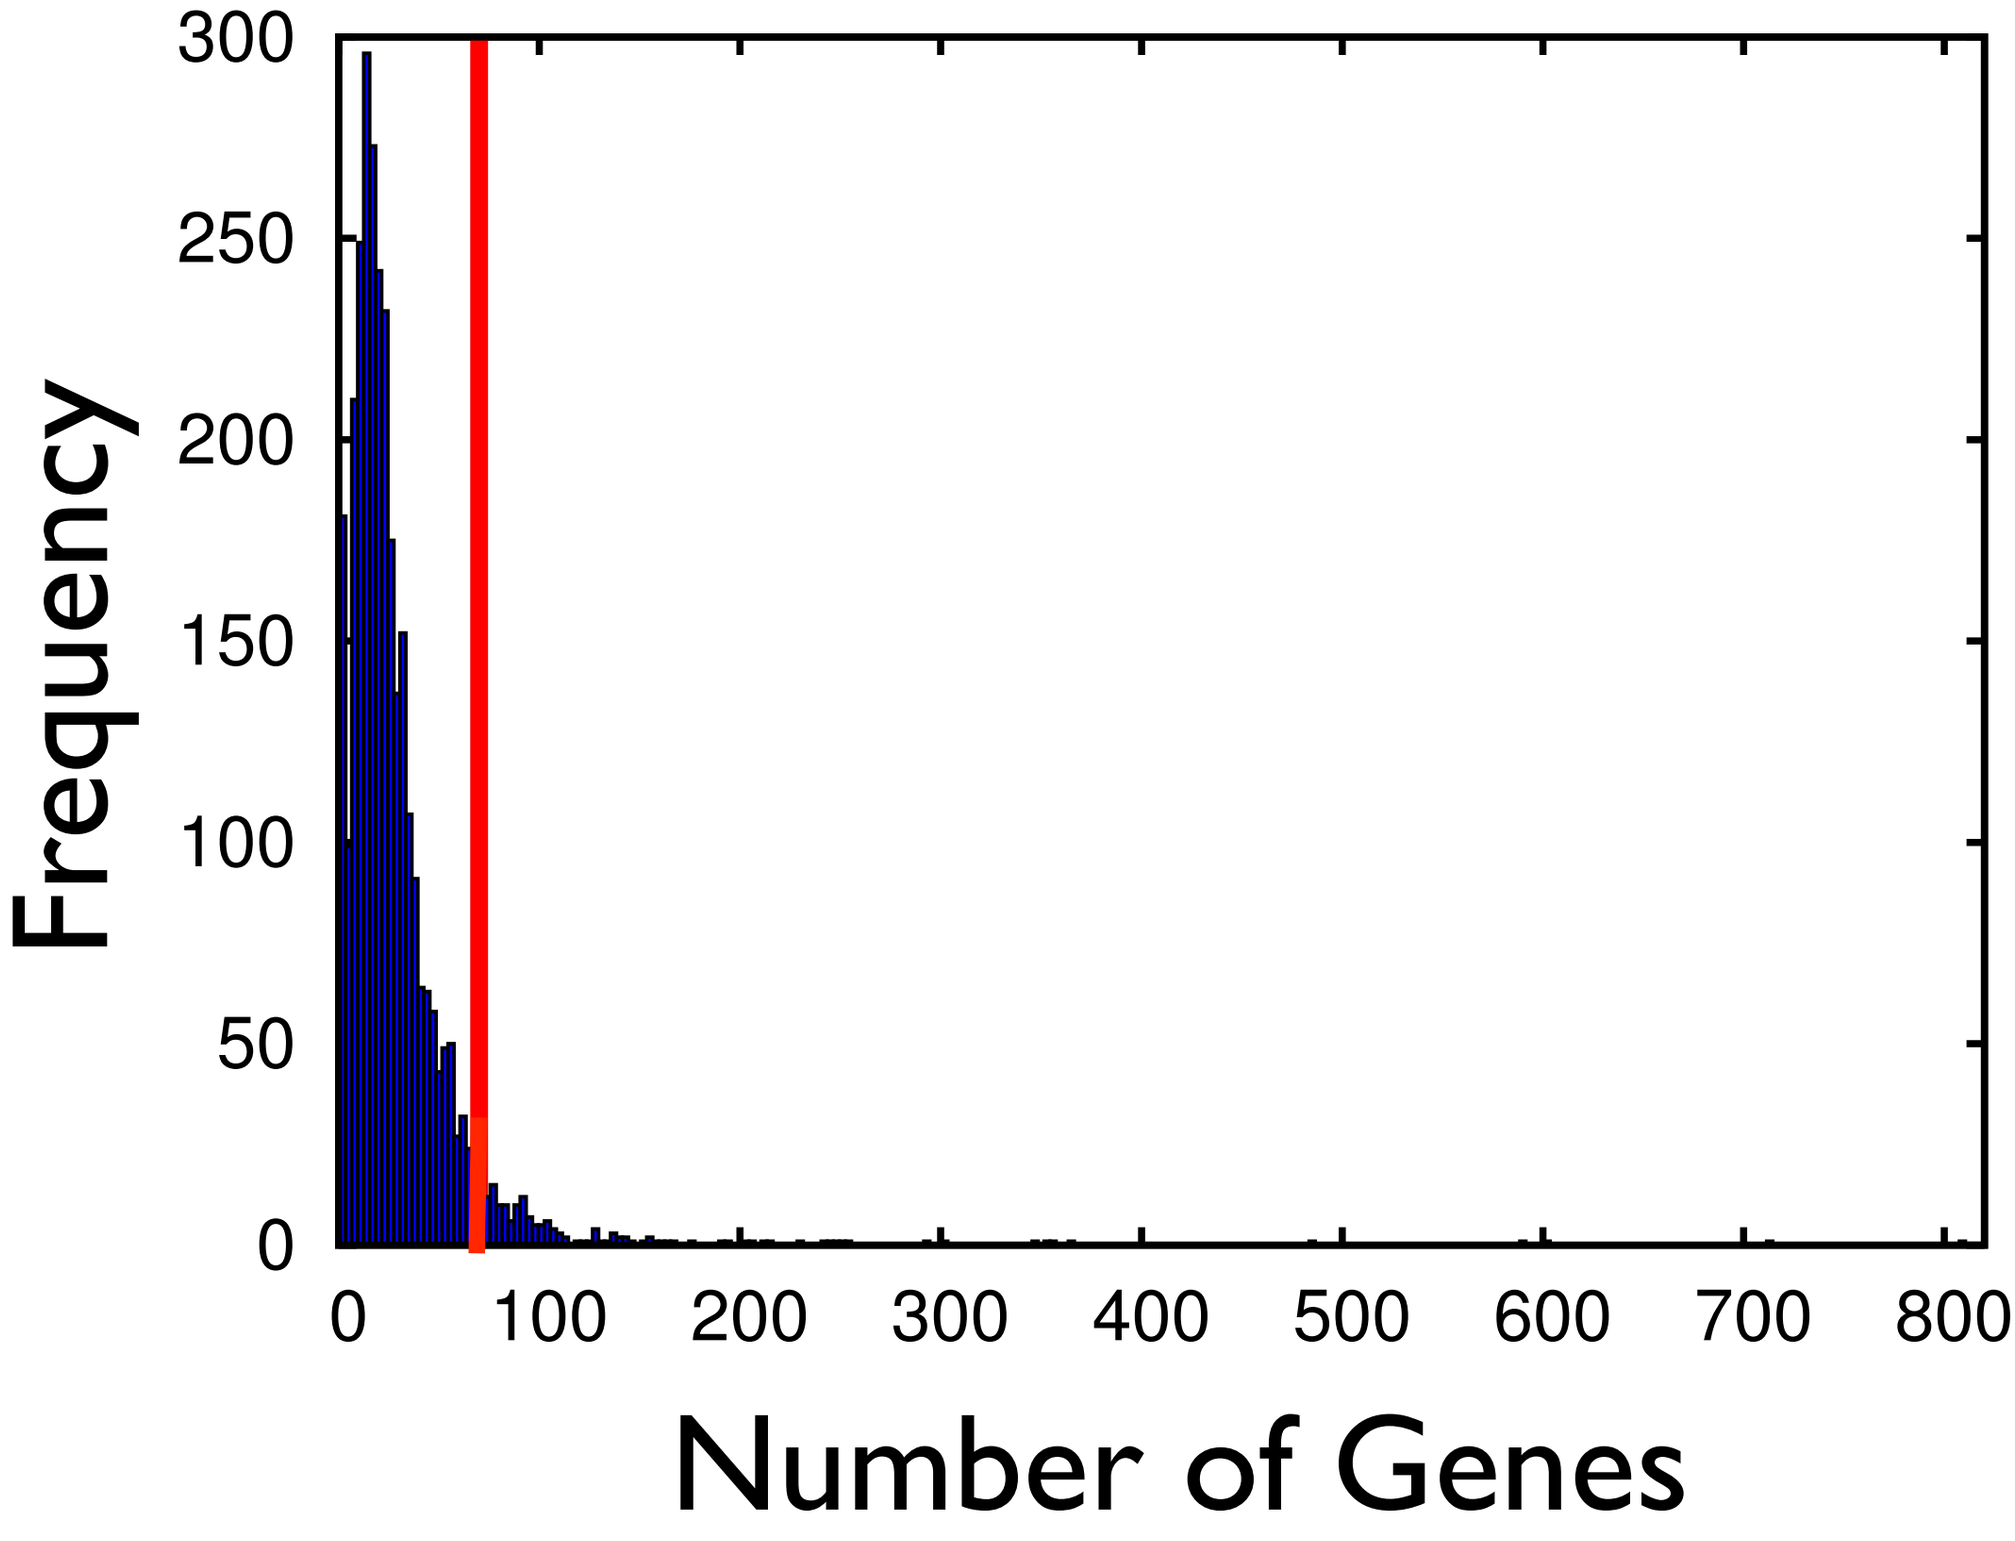
Varied nuclear shape: spherical, ellipsoidal

Passive and active confinement

GeneCards: Rebhan,M., Chalifa-Caspi,V., Prilusky,J. and Lancet,D. (1998) GeneCards: a novel functional genomics compendium with automated data mining and query reformulation support. Bioinformatics, 14, 656–664.

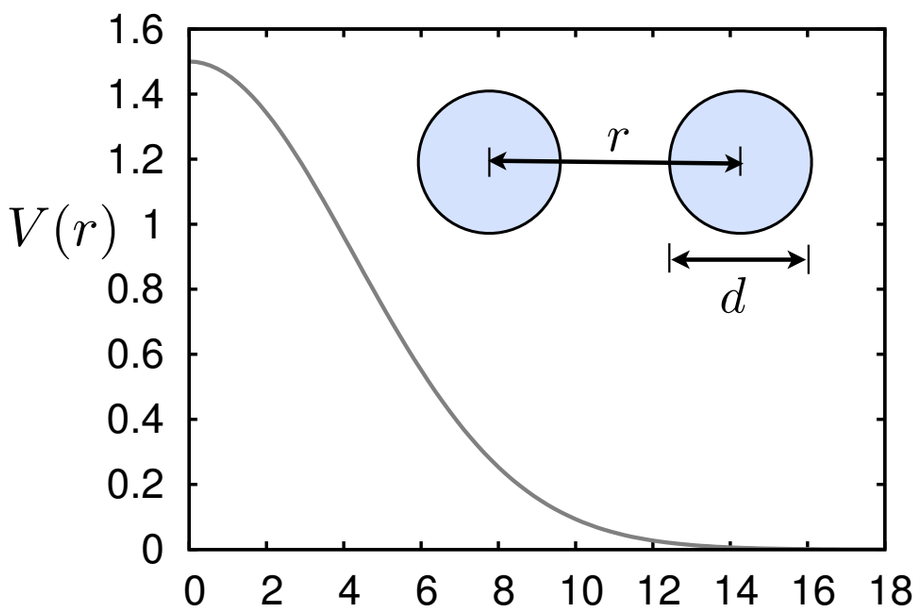


Assigning activity to each monomer, from gene densities



$$V_{neighbour\ monomers}(\mathbf{r}_i, \mathbf{r}_{i+1}) = \frac{1}{2}k(|\mathbf{r}_i - \mathbf{r}_{i+1}|)^2$$

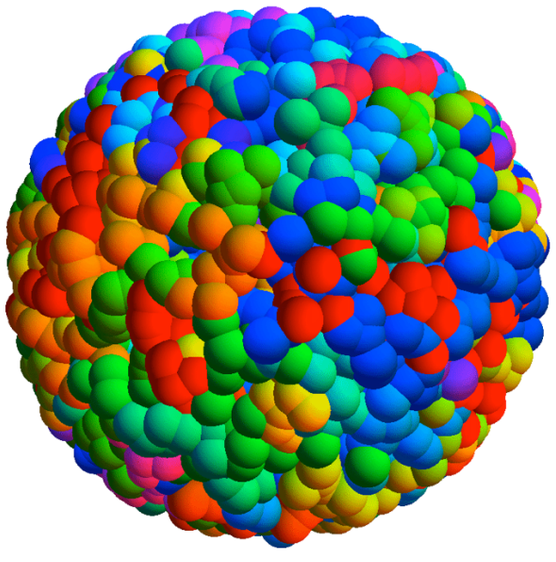
Monomer-Monomer Interactions



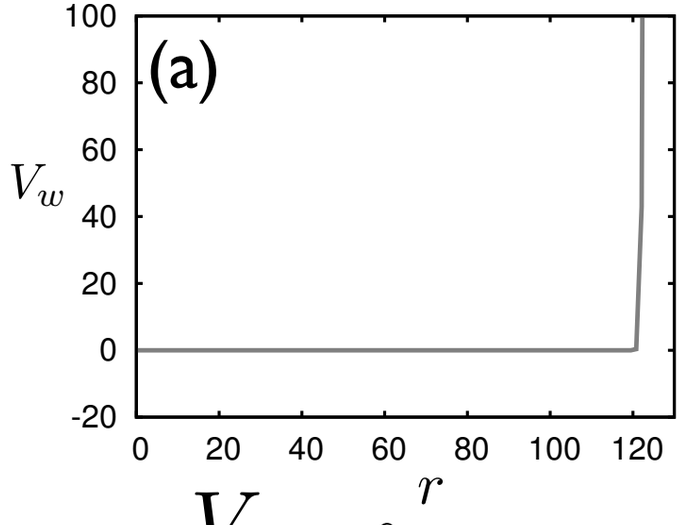
$$d \simeq 500nm,$$
$$R_0 \simeq 6.7\mu m$$
$$\ell_0 \simeq 600nm$$
$$V_0 \simeq 1.5 k_B T_{eq}$$

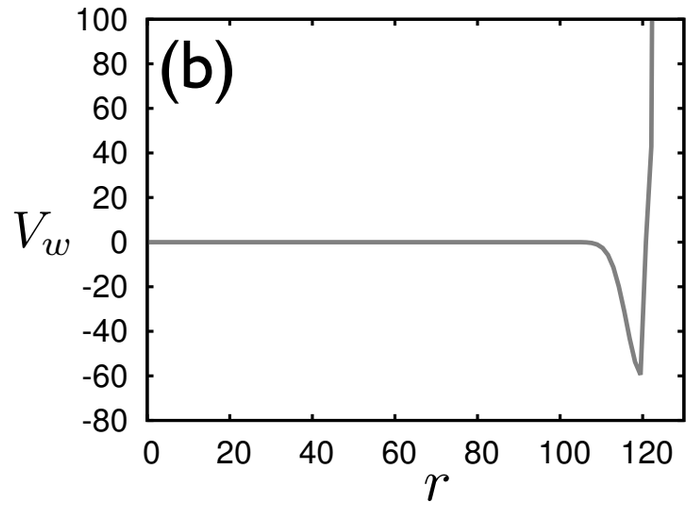
Self-repelling but not self-avoiding

$$V_{monomer-monomer}(\mathbf{r}_i, \mathbf{r}_j) = V_0 \exp\left(-|\mathbf{r}_i - \mathbf{r}_j|^2/\sigma^2\right)$$



Monomer-Wall Interactions





$$V_{wall}(\mathbf{r}_i) = \frac{V_{conf}}{a^5}(|\mathbf{r}_i| - R_0)^5, \qquad |\mathbf{r_i}| > R_0$$

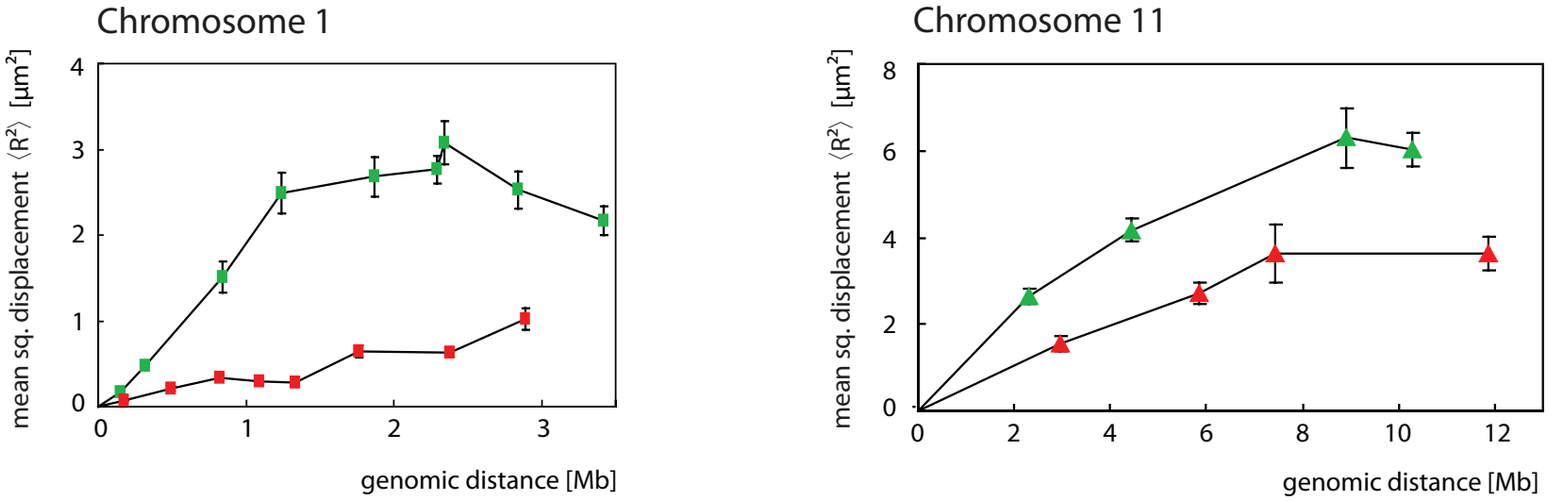
Mateos-Langerak et al, PNAS 2009



Models for large-scale chromosome structure

Rosette model

Helical fold model

Network model

Random loop model

Fractal globule model + ...

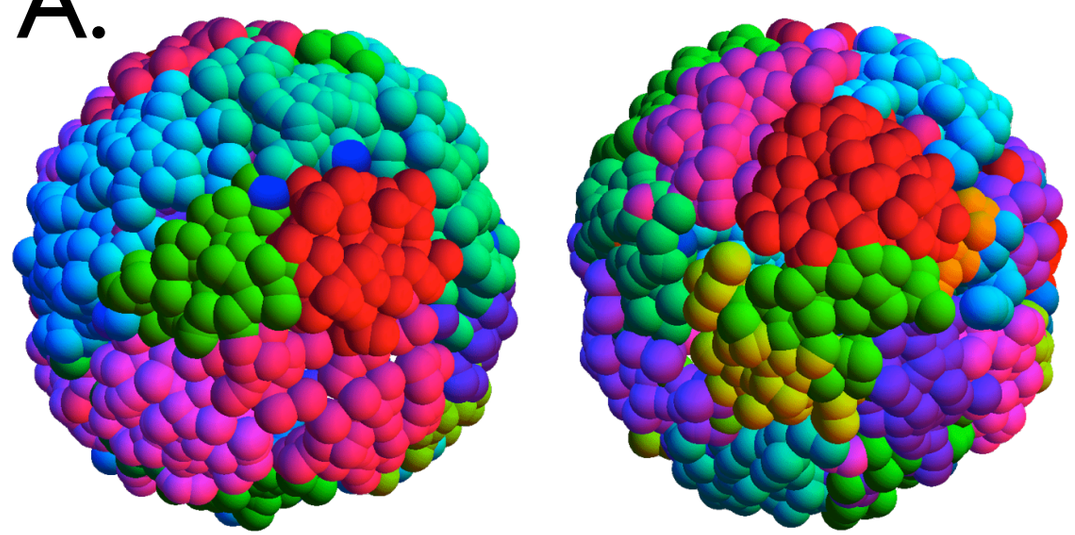
P.M. Diesinger and D.W. Heermann, Biophys. J. (2009)

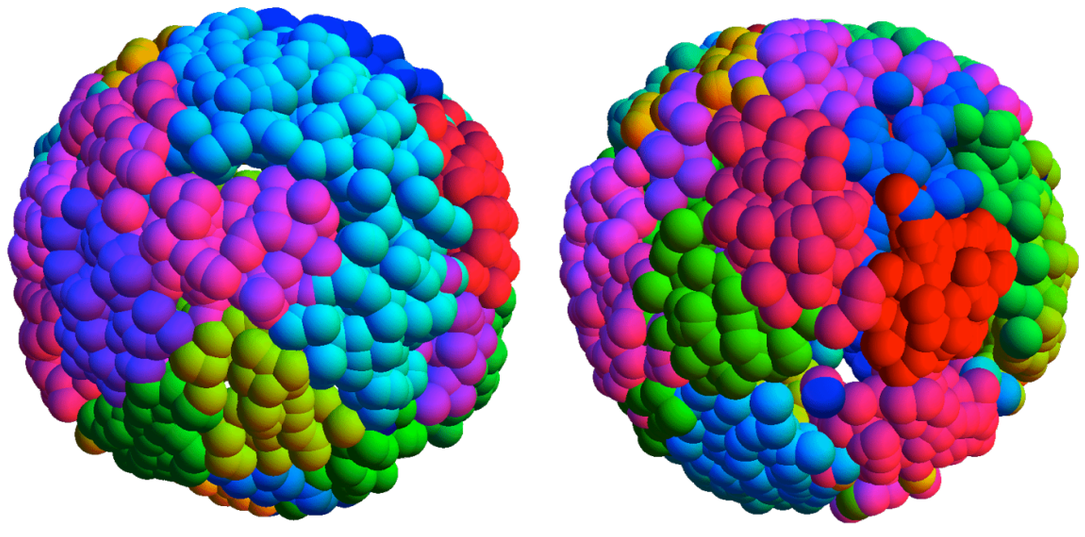
We implement the random loop model

Our model chromosomes are now compact on large scales

Can compactness and inhomogenous activity generate “chromosome territories”?

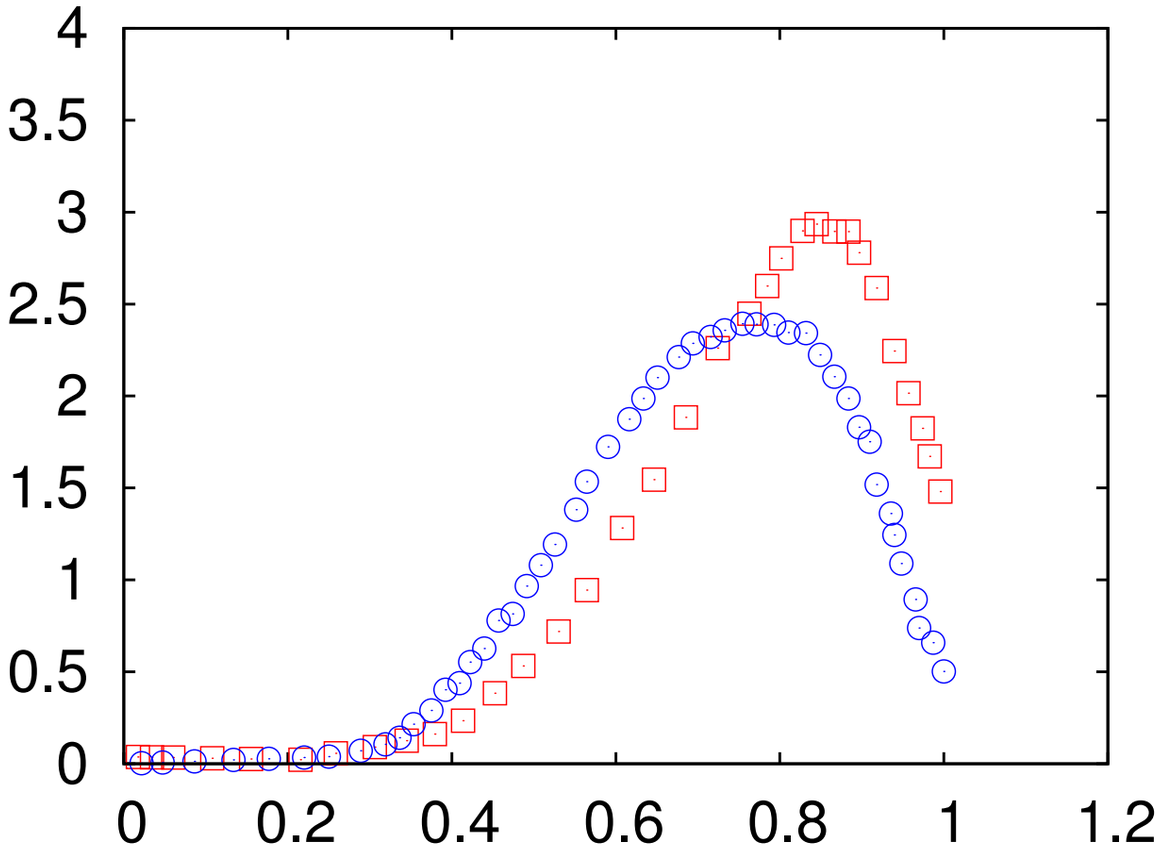
A.

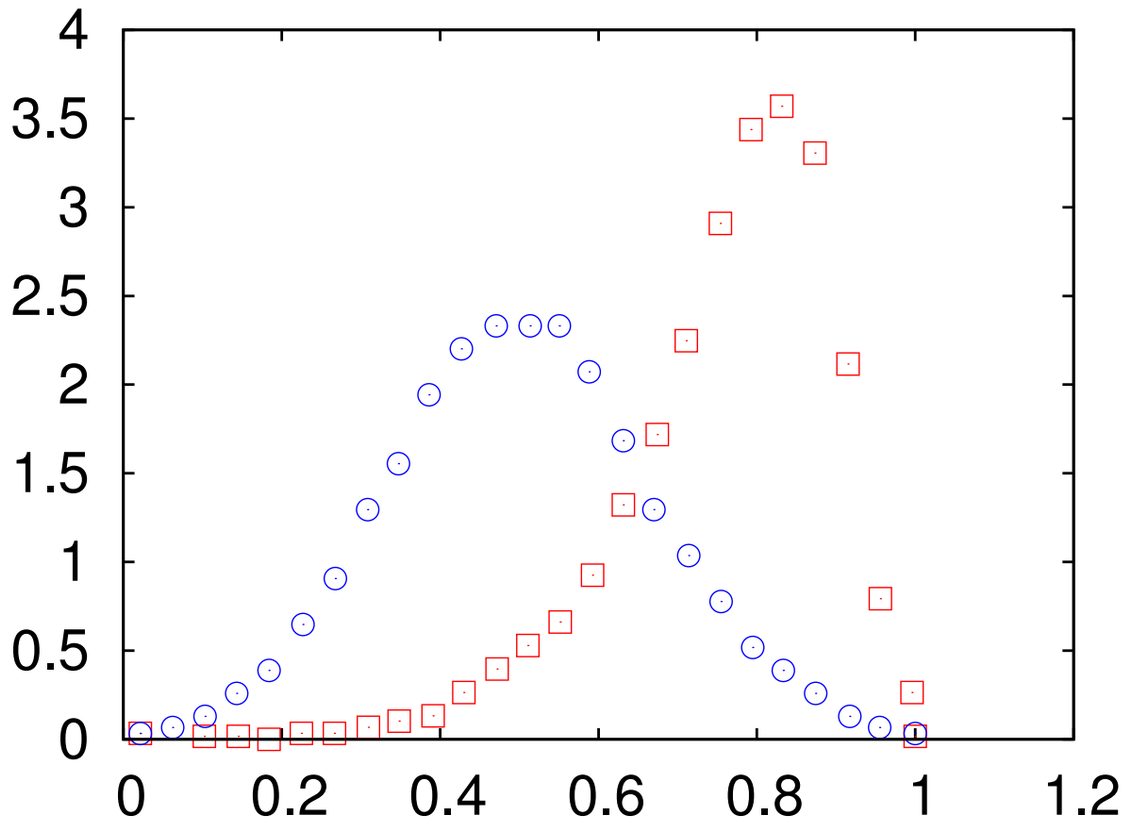




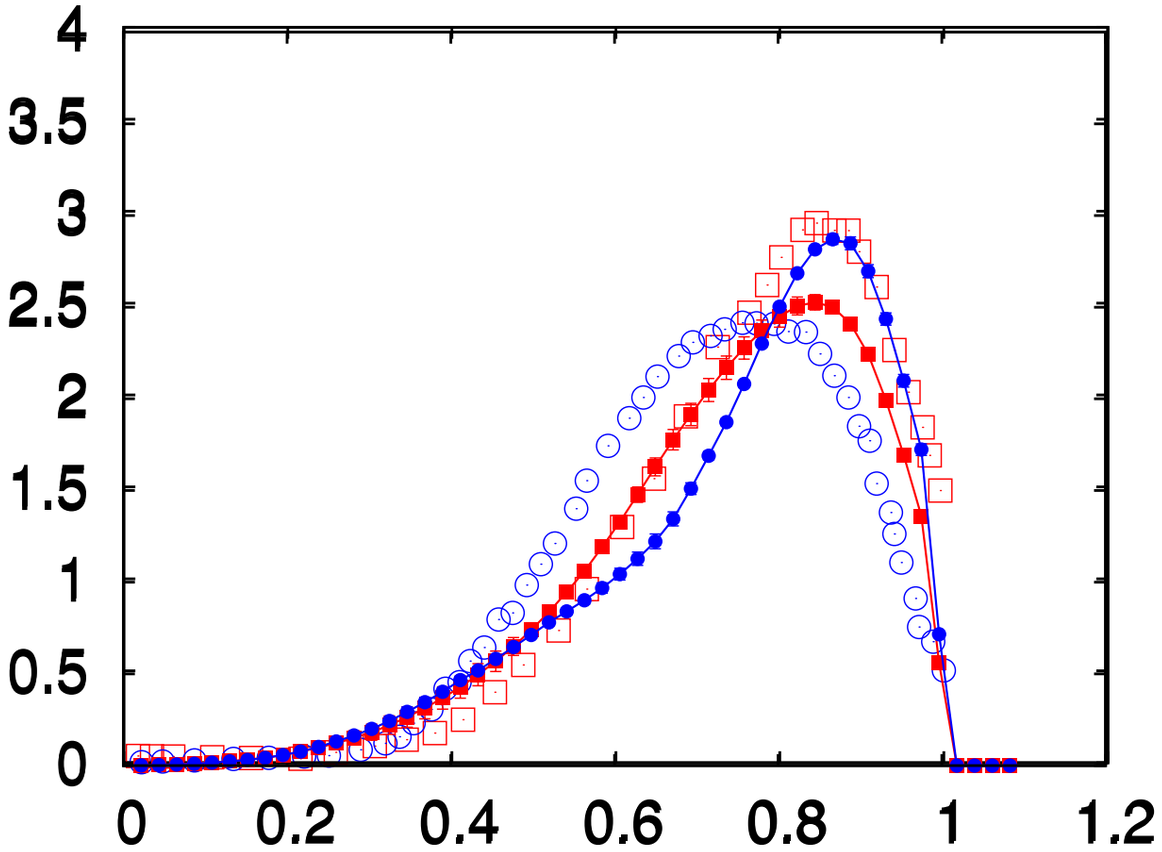
Yes

With inhomogeneous activity and compactness at large scales, how does our model compare to data?



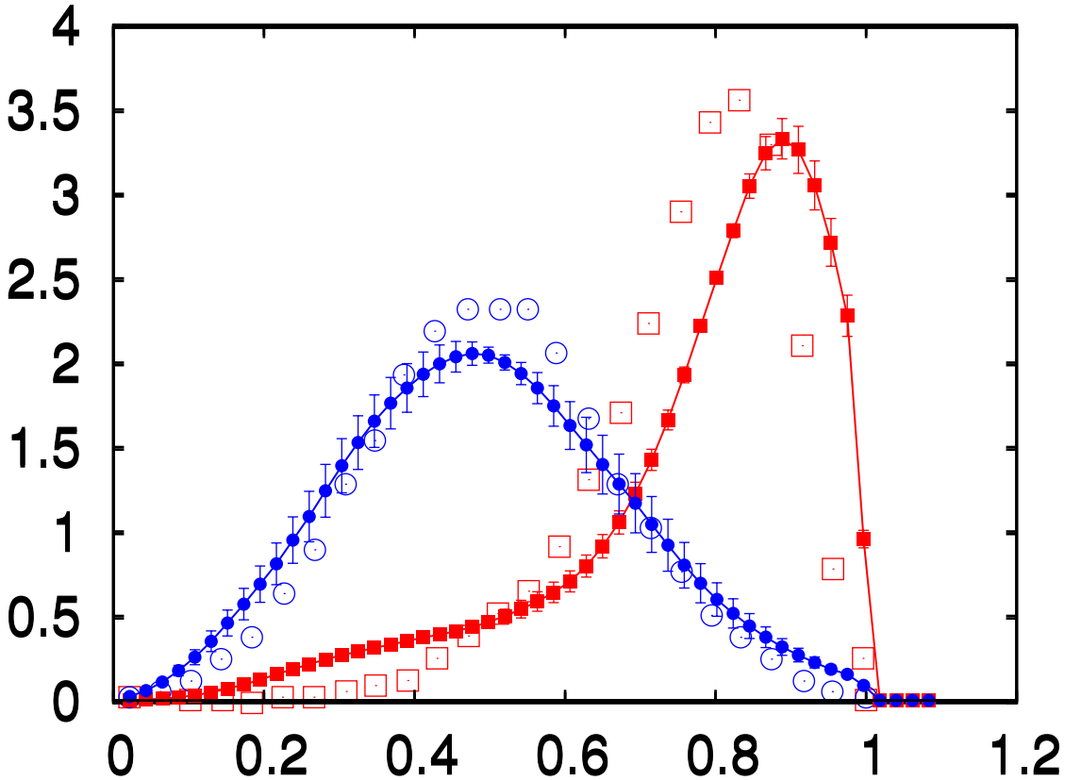


With inhomogeneous activity and compactness at large scales, how does our model compare to data?

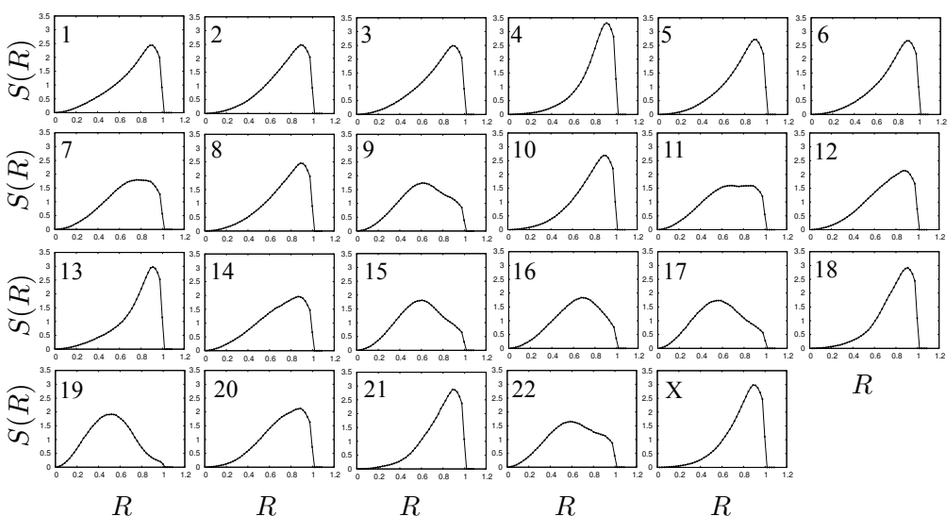


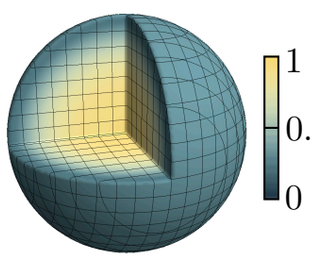
Reasonably well, despite the utter simplicity of the model

Chromosome 18/19



Chromosome 12/20





Positioning correlates to chromosome size? Nuclear shape?

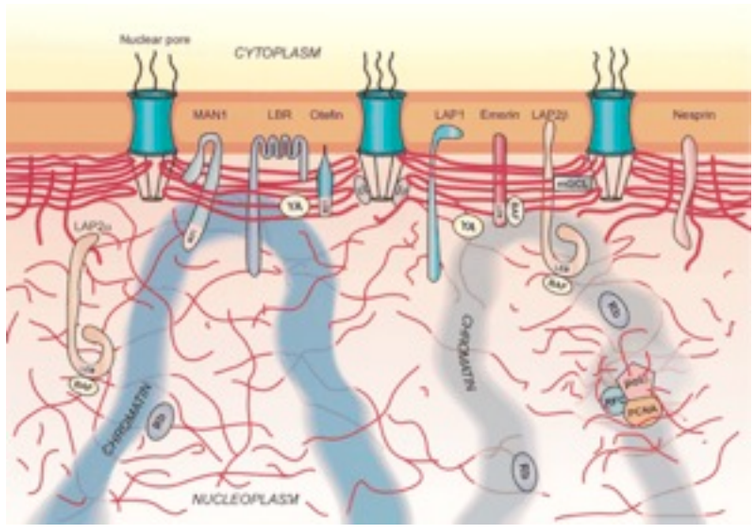
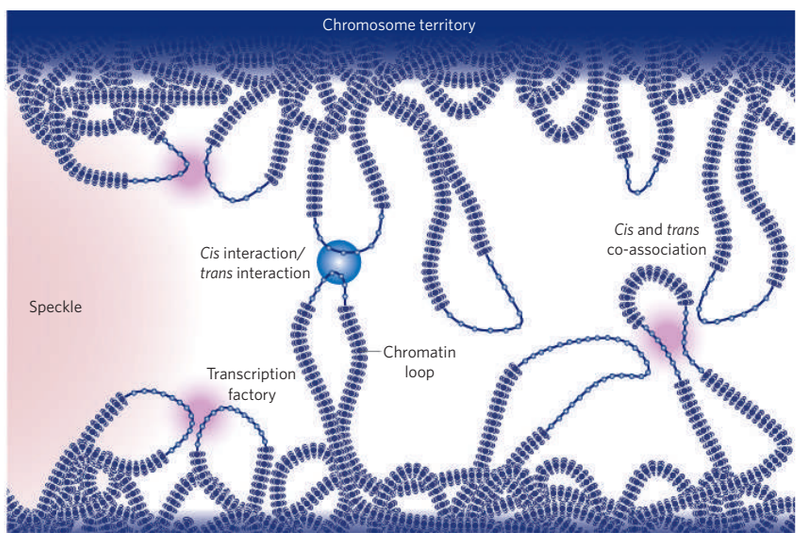
Caution: Not so fast ...

Lamins and nuclear architecture/ chromatin structuring?



Goldman et al, Genes Dev (2002)

Importance of relative positioning, transcription factories, looping ... ?

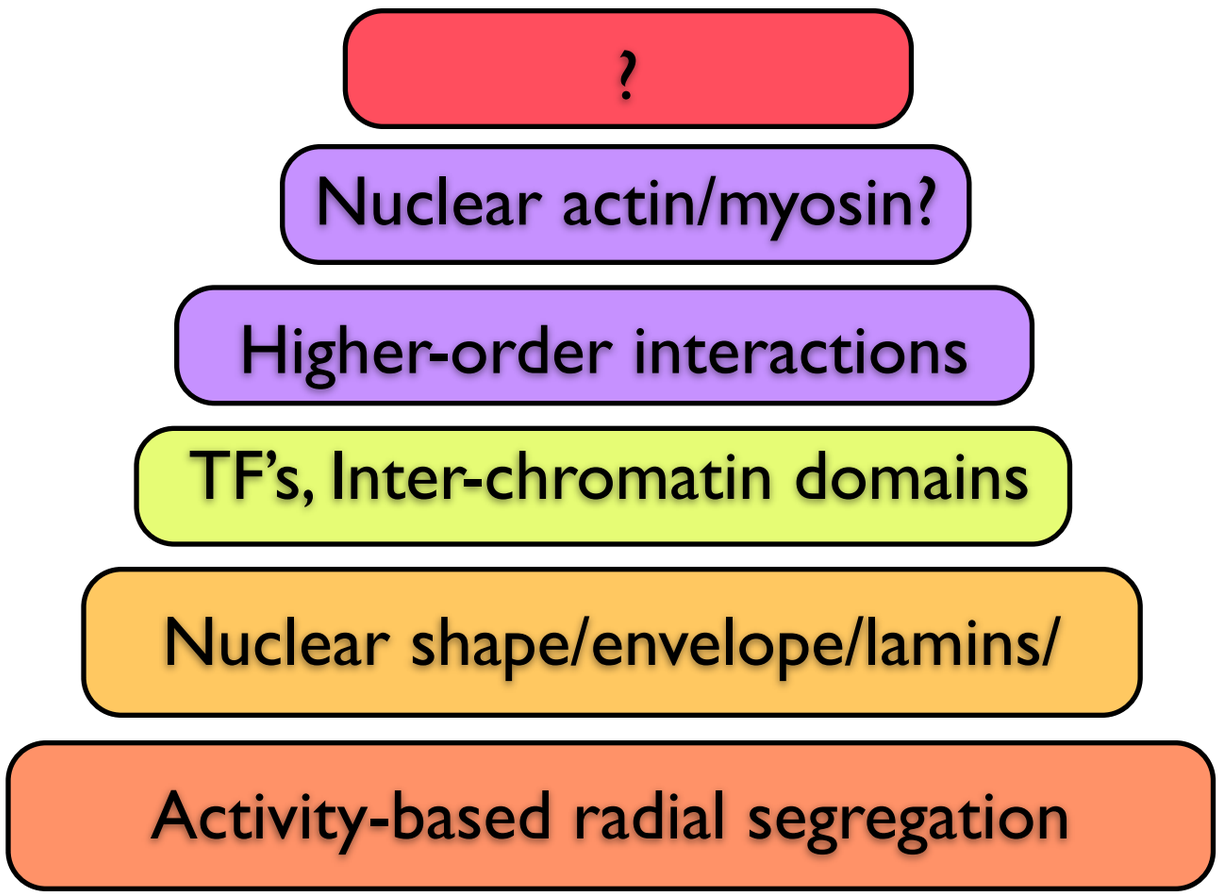


Fraser and Bickmore, Nature (2007)

Very far from these ..

A hierarchy of positioning drivers ... ?

Increasing complexity



Activity- based radial segregation might provide a generic initial template for local physical and biochemical events acting to further stabilize and optimize positioning

Conclusions

1. Chromatin as a model system for active matter

2. Suggest: Segregation by gene density and the formation of chromosome territories have a common origin in "activity-based segregation"

3. Inhomogeneous activity, confinement and polymeric nature of chromosomes are central

Nucleic Acids Research Advance Access published January 22, 2014

Nucleic Acids Research, 2014, 1–15
doi:10.1093/nar/gkt1417

Chromosome positioning from activity-based segregation

Nirmalendu Ganai[1], Surajit Sengupta[2,3] and Gautam I. Menon[4,5,6,*]

The discovery of distinct radial positions of chromosomes and genes has changed the way we think about genome organization. It has highlighted the non-randomness of higher-order genome organization and it has inspired the pursuit of how spatial genome organization contributes to function.
