# Cataclysmic variables

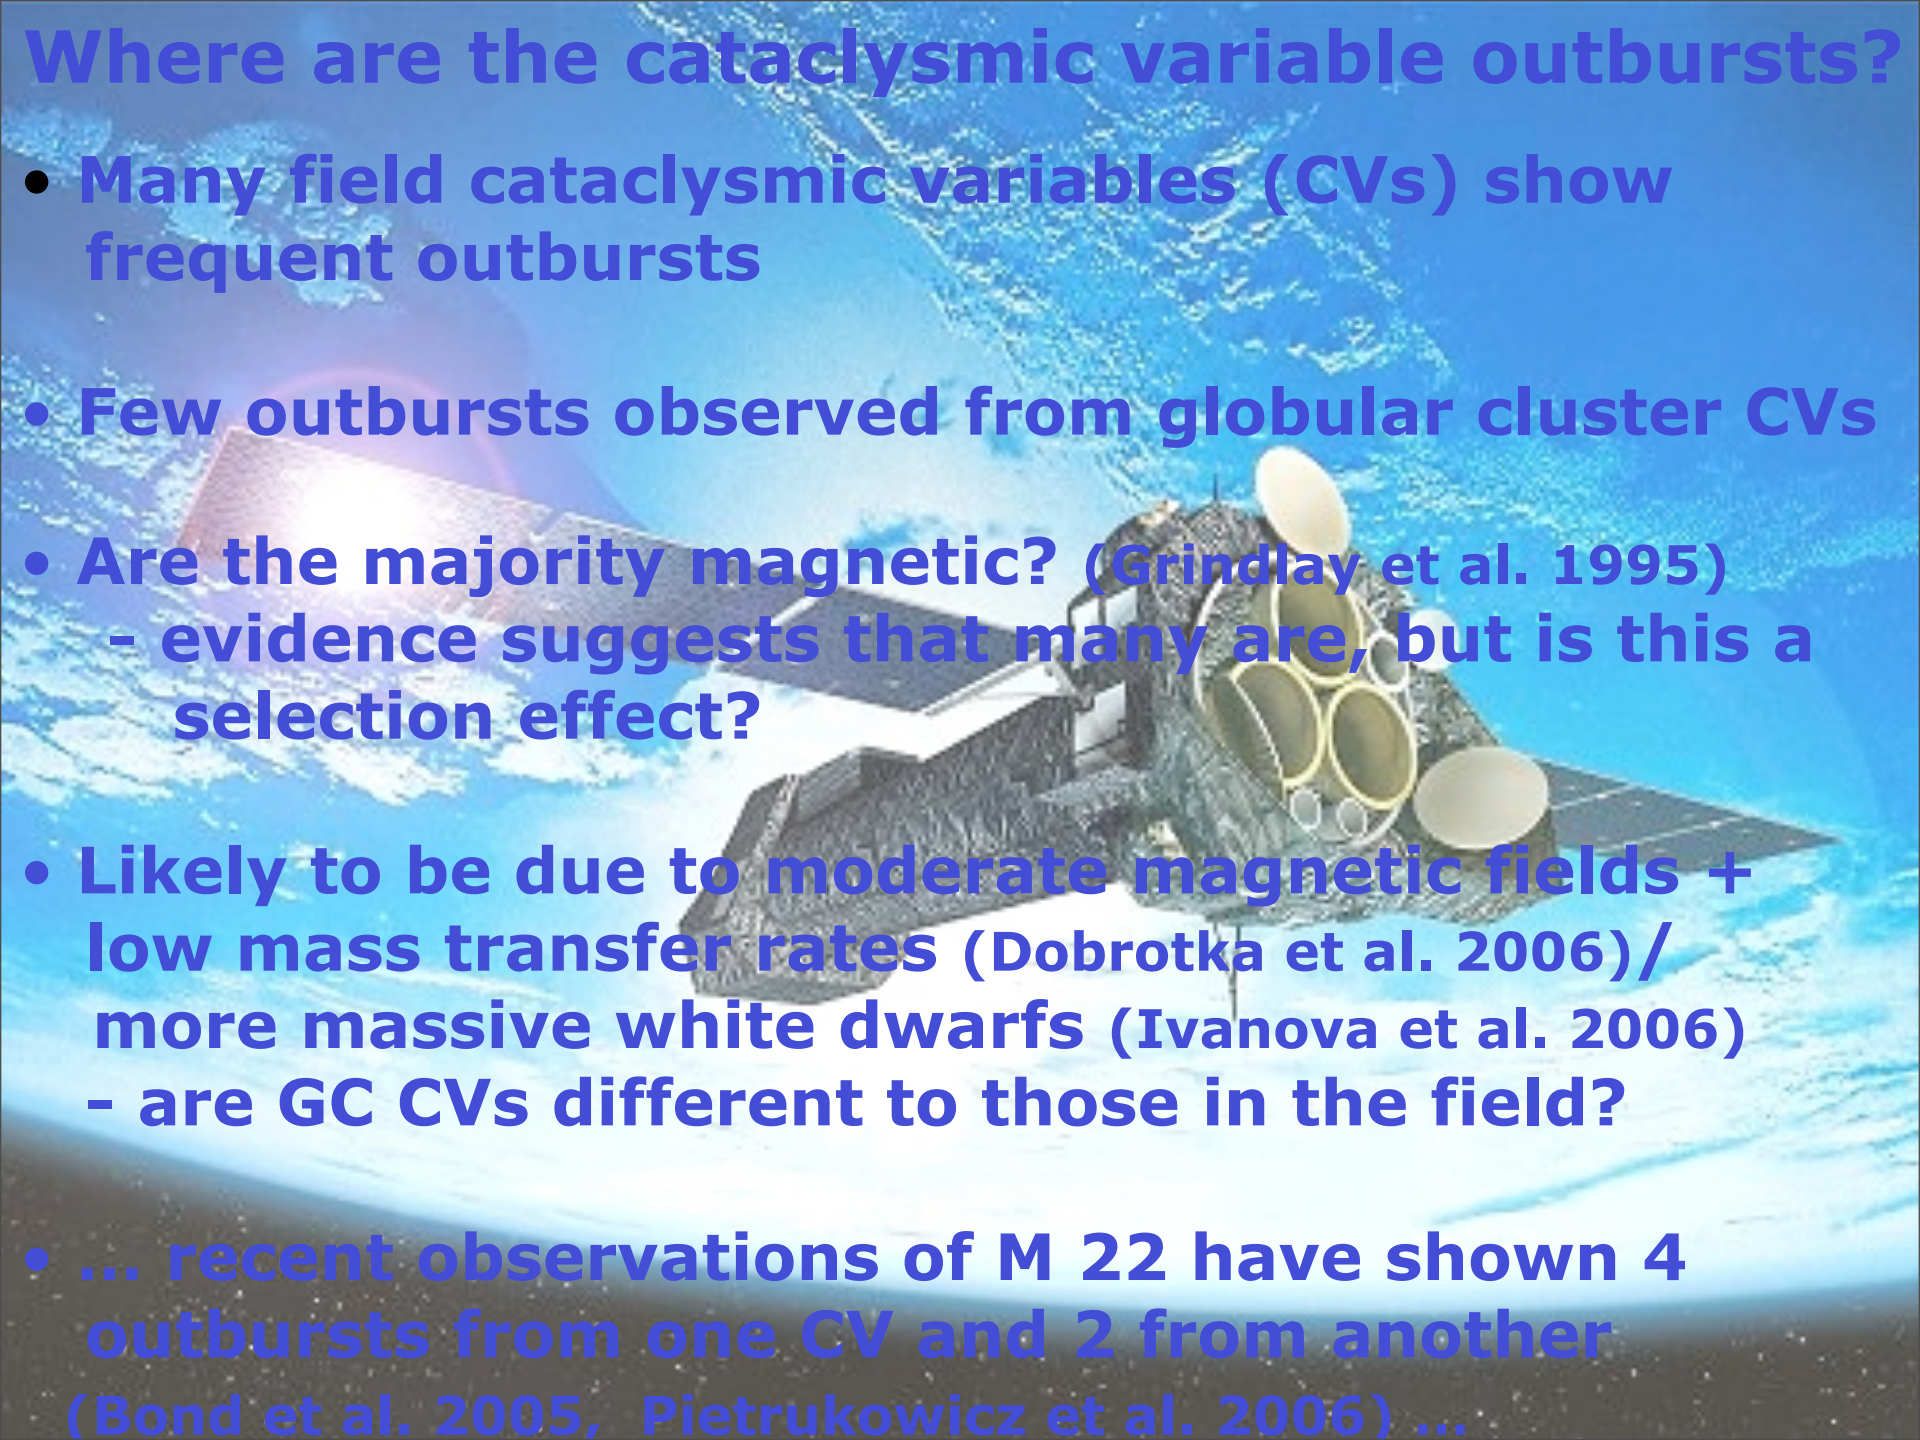

# Cataclysmic variables

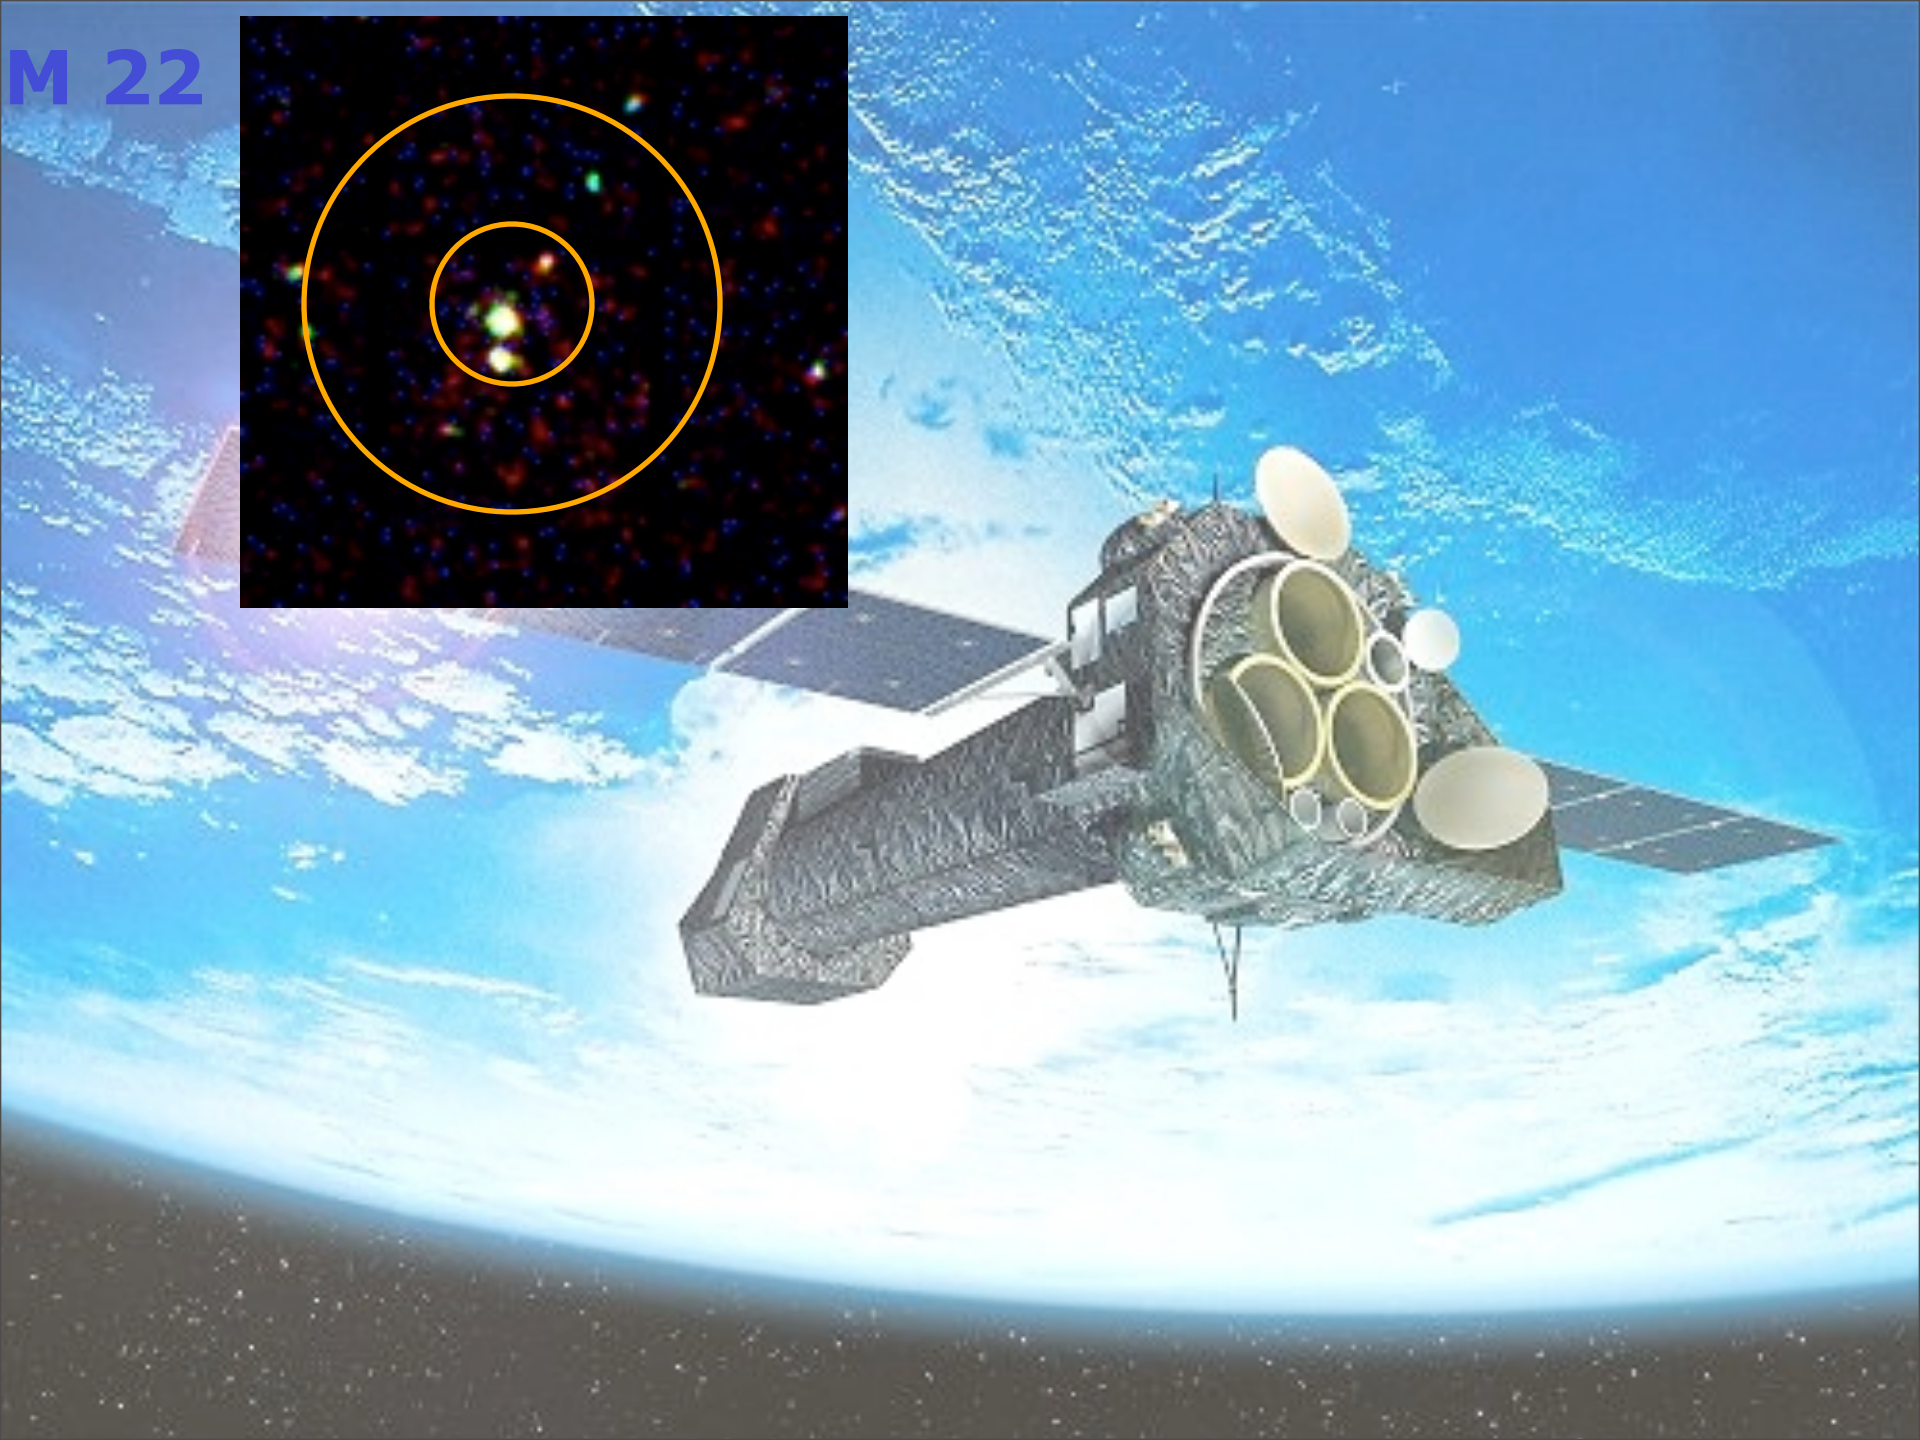

# Cataclysmic variables

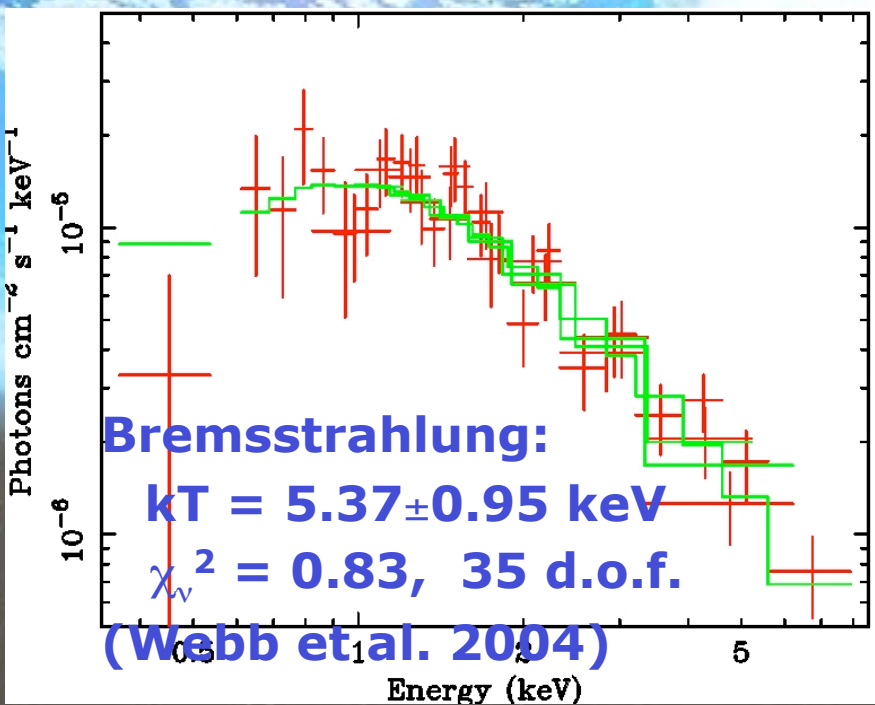

# Where are the cataclysmic variable outbursts?

- Many field cataclysmic variables (CVs) show frequent outbursts
  - Few outbursts observed from globular cluster CVs
  - Are the majority magnetic? (Grindlay et al. 1995)
    - evidence suggests that many are, but is this a selection effect?
  - Likely to be due to moderate magnetic fields + low mass transfer rates (Dobrotka et al. 2006)/ more massive white dwarfs (Ivanova et al. 2006)
    - are GC CVs different to those in the field?
  - ... recent observations of M 22 have shown 4 outbursts from one CV and 2 from another (Bond et al. 2005, Pietrukowicz et al. 2006) ...
-

Also UV and X-ray observations of NGC 2808 indicate two populations of CVs – estimates made to determine fractions of non-mag/mag. CVs (Servillat et al. 2008)

# Are GC CVs inherently different to Galactic plane CVs?

- Many GC CVs discovered through X-ray observations
  - Many new CVs found in the 2XMM catalogue :
    - 2XMMi released 20th August 2008
    - 289083 X-ray source detections
    - 221012 unique X-ray sources
  - Follow-up of these sources is allowing us to compare the two X-ray selected populations
  - Population studies of known catalogue sources has enabled identification of unknown sources
  - Initial population study of all the 2608 variable sources
- 
- A satellite is shown in space, with a bright sun in the background. The satellite has several large, circular instruments or sensors. The background is a deep blue space with some light trails and a bright sun on the left side.

# Variable sources in 2XMMi

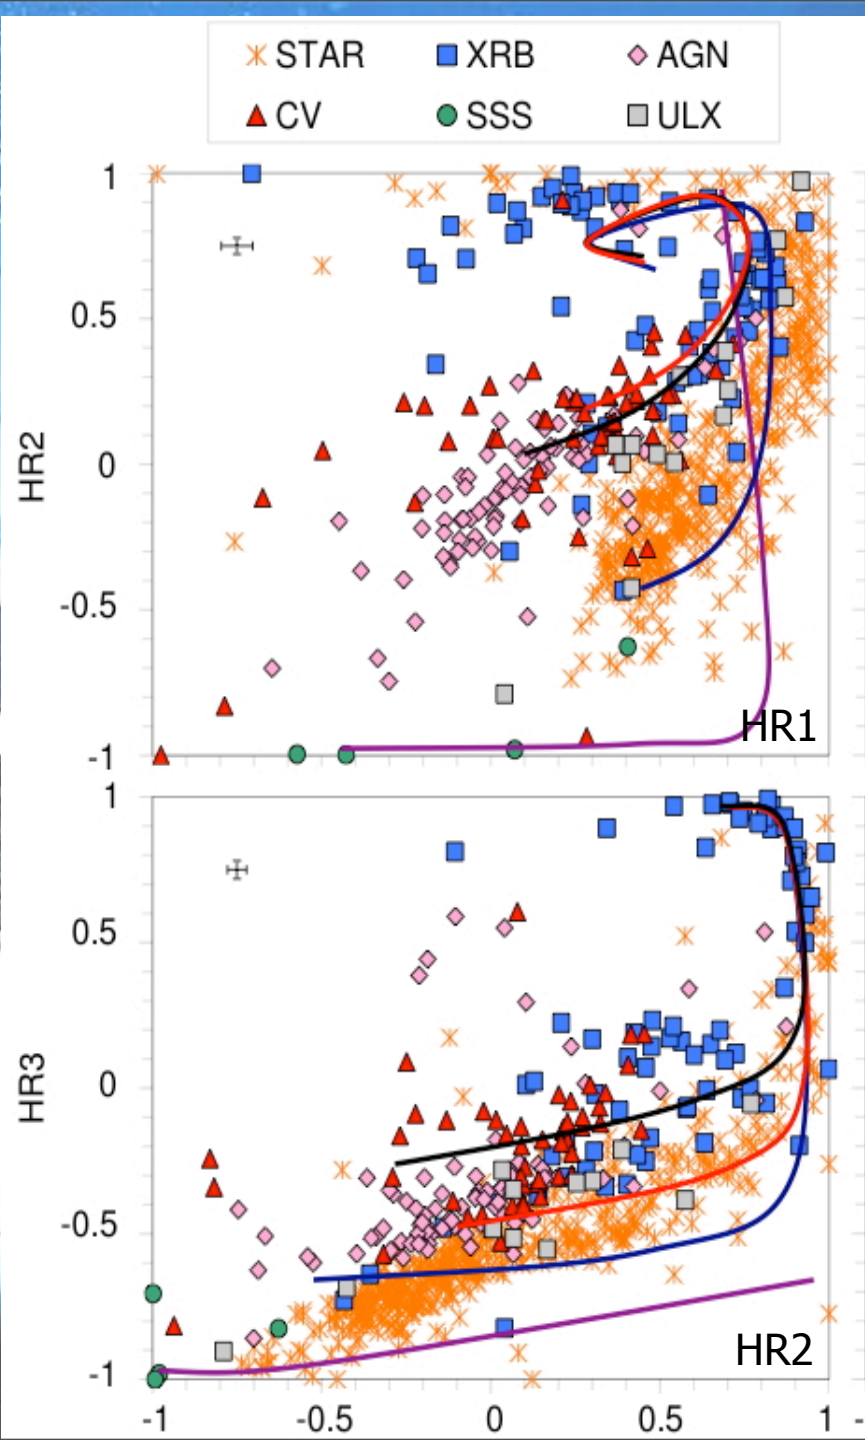

Band 1 = 0.2 – 0.5 keV  
Band 2 = 0.5 – 1.0 keV  
Band 3 = 1.0 – 2.0 keV  
Band 4 = 2.0 – 4.5 keV  
Band 5 = 4.5 – 12.0 keV

HR1 =  $\frac{\text{Band 2} - \text{Band 1}}{\text{Band 2} + \text{Band 1}}$

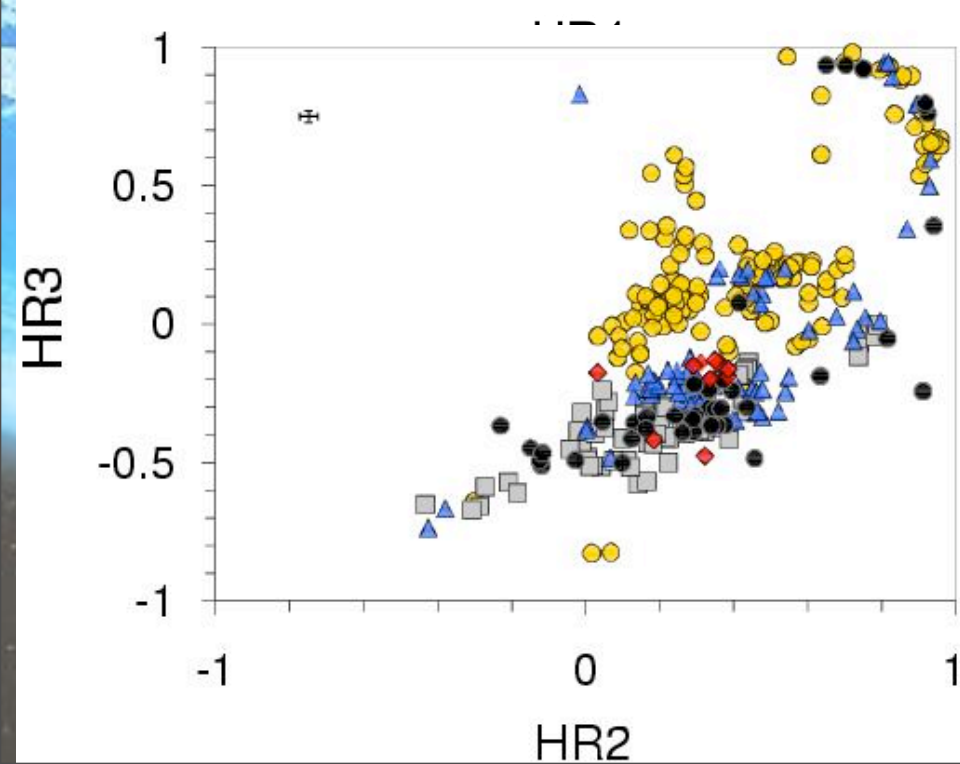

HR2 =  $\frac{\text{Band 3} - \text{Band 2}}{\text{Band 3} + \text{Band 2}}$

HR3 =  $\frac{\text{Band 4} - \text{Band 3}}{\text{Band 4} + \text{Band 3}}$

HR4 =  $\frac{\text{Band 5} - \text{Band 4}}{\text{Band 5} + \text{Band 4}}$

updated 8 December 2006

Lattimer & Prakash (2007)

# Radii

One possible constraint

Redshifted absorption lines in spectrum of  
EXO 0748-676 (strongly debated)

⇒  $R \geq 13.8 \pm 1.8$  km (Özel 2006)

# Radii

One possible constraint

Redshifted absorption lines in spectrum of  
EXO 0748-676 (strongly debated)

⇒  $R \geq 13.8 \pm 1.8$  km (Özel 2006)

Alternatively

Mass + radius can be determined from X-ray spectra  
If the distance is known:

$$F_{\infty} = (R_{\infty}/d)^2 \sigma T_{\infty}^4 \quad \text{and} \quad R_{\infty} = R / (1 - 2GM/Rc^2)^{0.5}$$

F = flux, R = radius, d = distance,  $\sigma$  = S-B constant

0.5-1.0 keV

1.0-2.0 keV

2.0-4.5 keV

# Quiescent neutron star low mass X-ray binaries in globular clusters

Distance well constrained

0.5-1.0 keV

1.0-2.0 keV

2.0-4.5 keV

Very soft X-ray spectra,  $T \sim 50\text{eV}$

Approximate blackbody spectra

Hydrogen atmosphere models give more realistic radii

Recent improvements to H atmos. models include (among others) :

- variety of surface gravities
- opacity due to absorption/scattering
- self irradiation by photons from NS

# Conclusions

Numerous binary systems found using XMM-Newton observations of Galactic globular clusters (GGC)

Investigation underway as to why GGC CVs have been observed to show so few outbursts

Moderate He II lines in optical CV spectra may imply moderate B fields that could inhibit outbursts

Evidence for black hole XRBs in M 31 GCs

Models using single surface gravities inappropriate

Equations of state for normal nucleonic matter preferred (although SQM possible)

Stiffest equations of state excluded
