

# Visiting Newton's Atelier before the Principia 1679-1684

Michael Nauenberg  
UC Santa Cruz

Oct 23, 2018

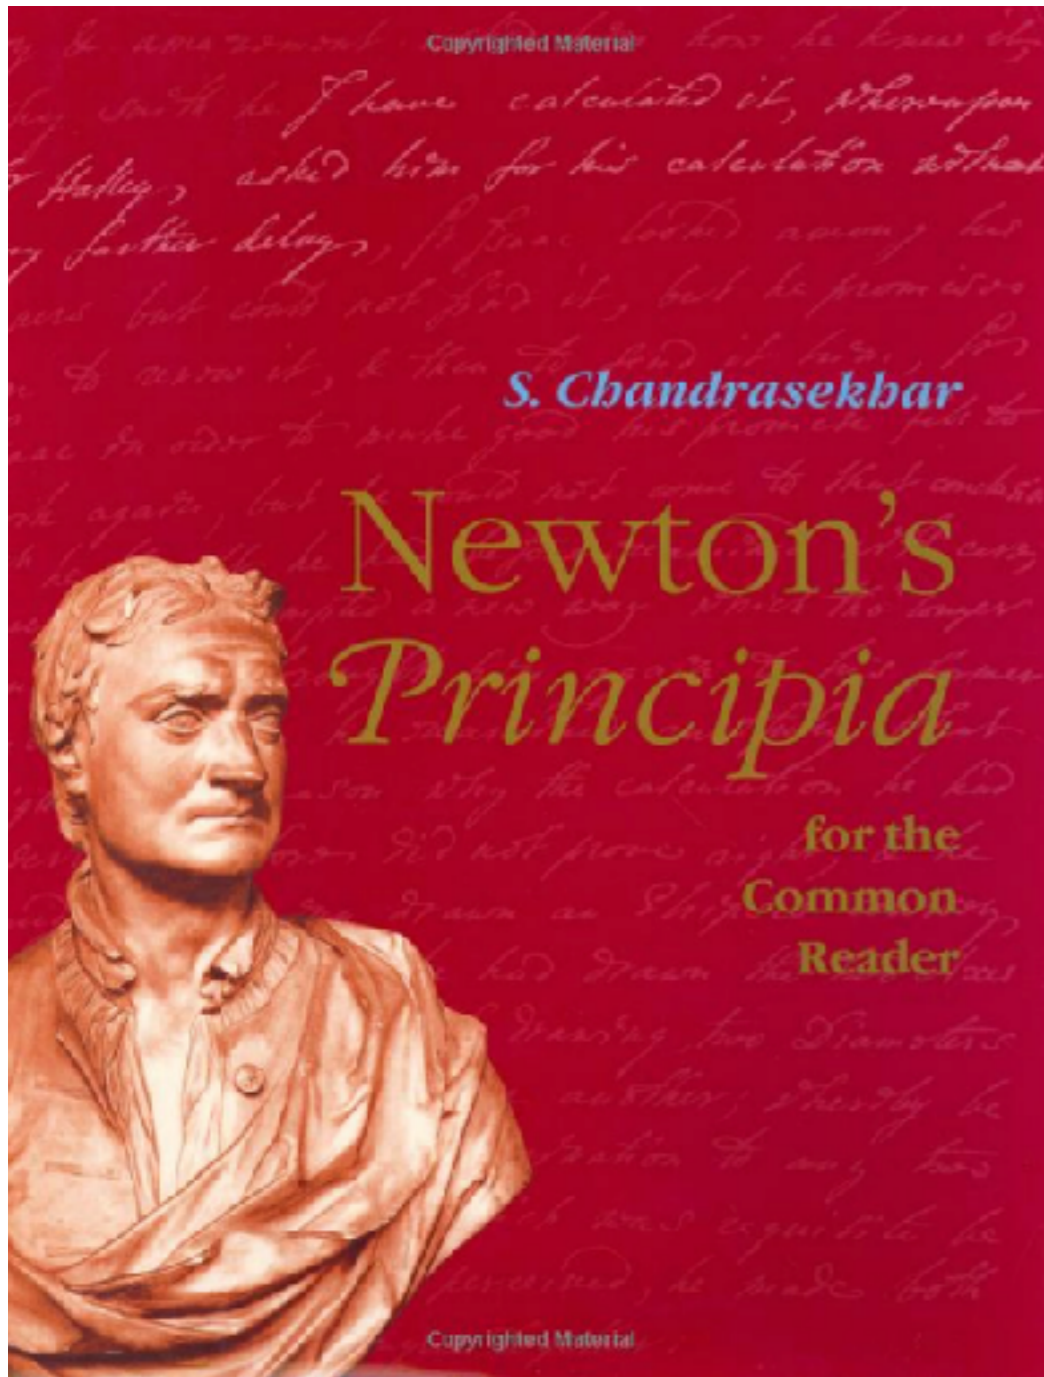

# Pierre Simon Laplace

## 1729-1847

This admirable work contains the germs of all the great discoveries that have been made since, about the system of the world: **the history of its development** by the followers of that great geometer will be at the same time the most useful comment on his work, as well as the best guide to arrive at new discoveries

Reading Newton became for  
Chandrasekhar a sustained  
epiphany:

“The view of science that he exhibit,  
the clarity with which he writes  
the number of new things that  
he finds, manifest a physical  
and mathematical insight  
of which there is no parallel  
in science at any time”

Scientific American,  
March 1994

**Analytical View of Sir Isaac  
Newton's Principia**

EDWARD JOHN ROUTH, BARON HENRY BROUGHAM  
BROUGHAM AND VAUX

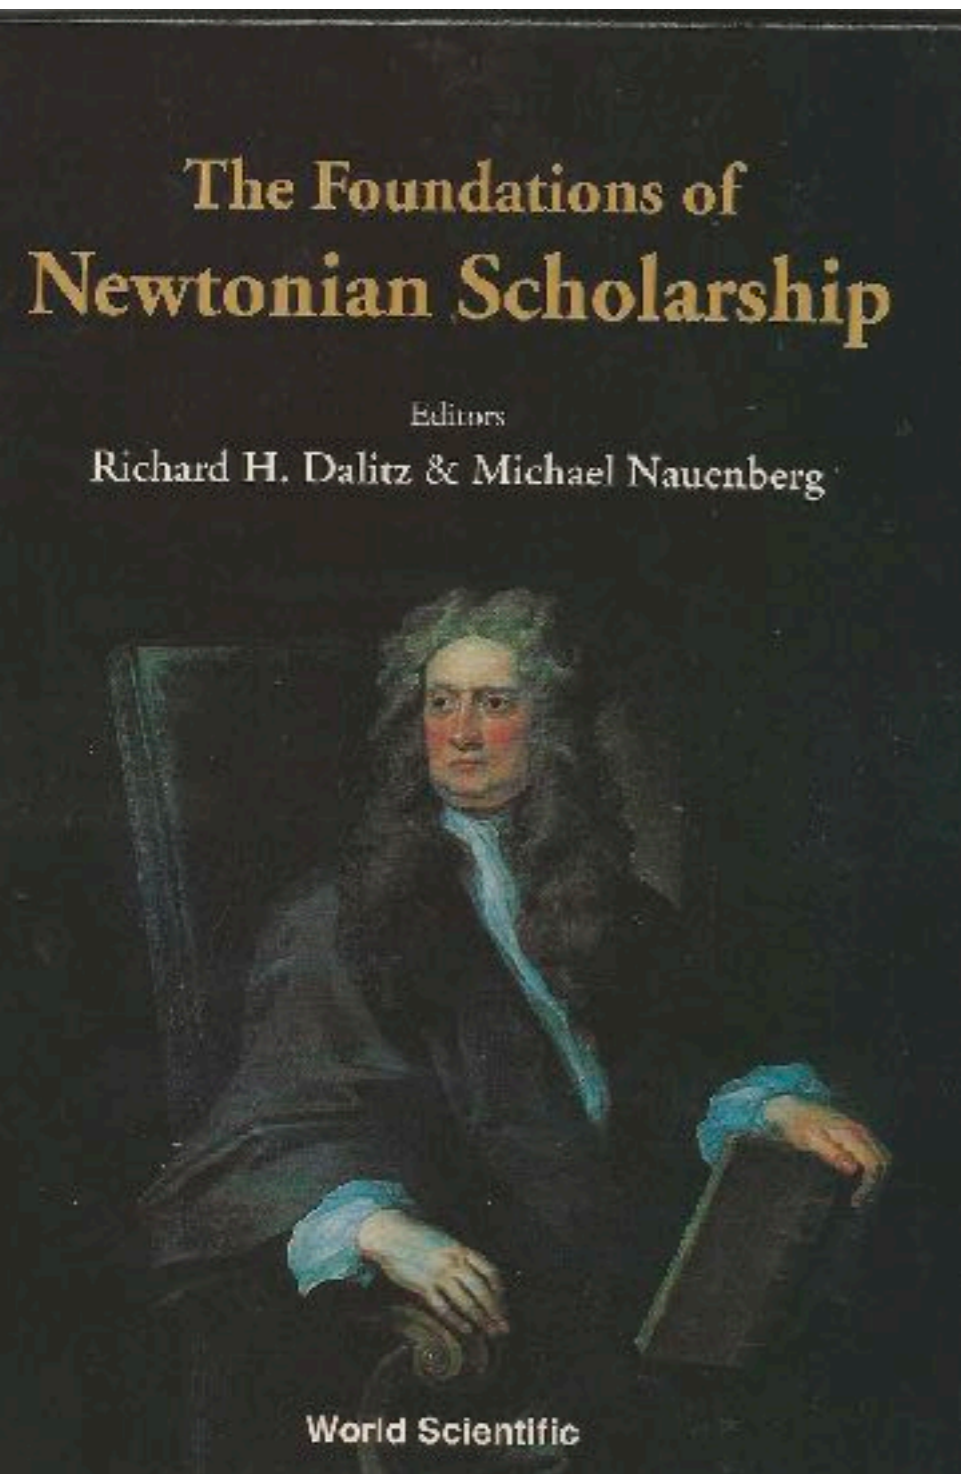

**NEWTON'S PRINCIPIA.**

**ANALYTICAL VIEW.**

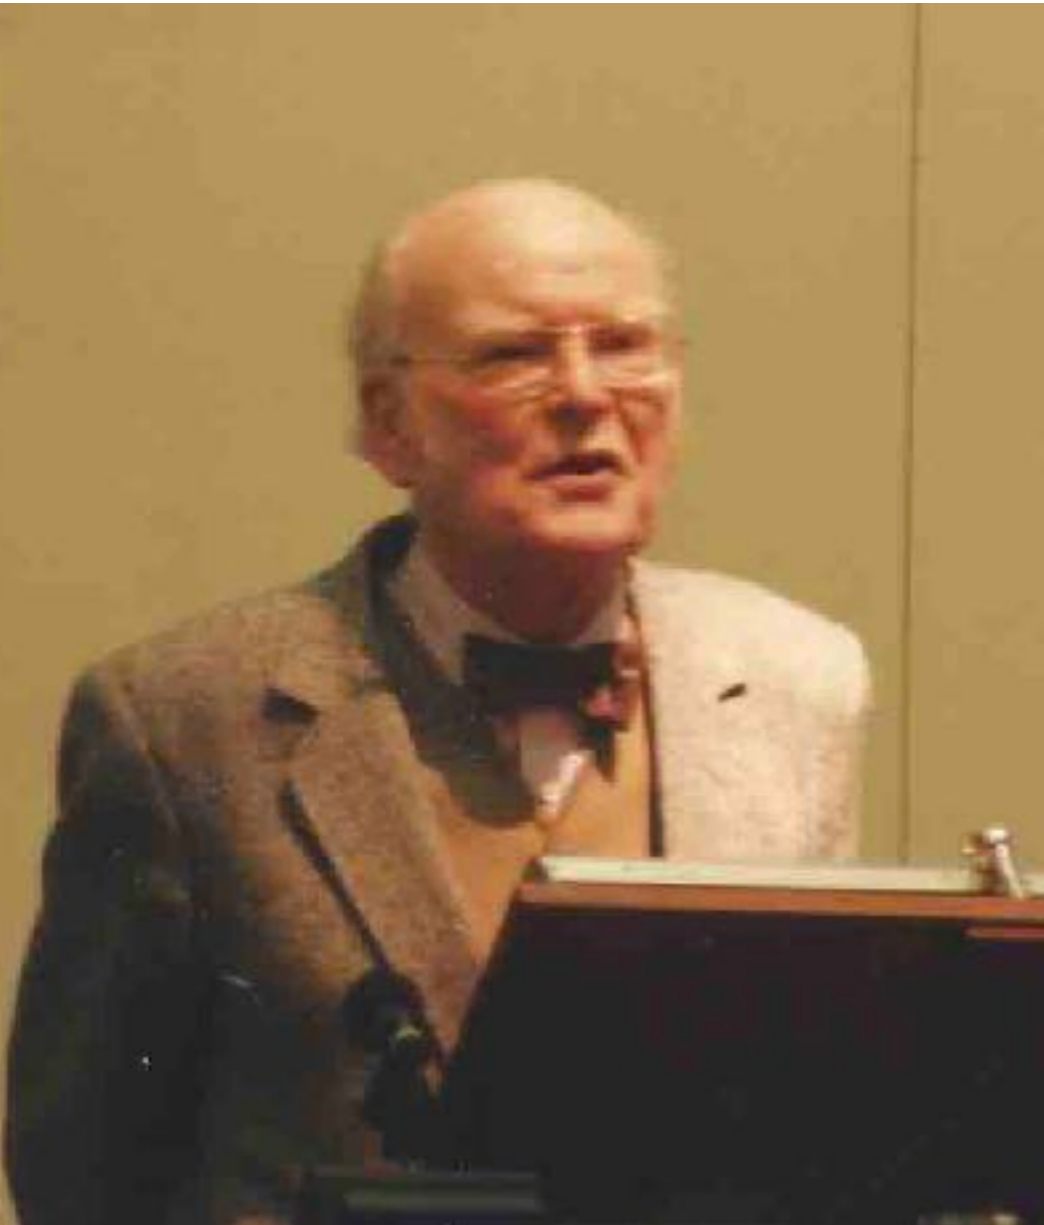

THIS work is justly considered by all men as the greatest of the monuments of human genius. It contains the exposition of the laws of motion in all its varieties, whether in free space or in resisting media, and of the action exerted by the masses or the particles of matter upon each other, those laws demonstrated by synthetic reasoning; and it unfolds the most magnificent discovery that was ever made by man — the Principle of Universal Gravitation, by which the system of the universe is governed under the superintendence of its Divine Maker.

“We now know that neither Principia nor Opticks sprang like Minerva from the head of Jove: they are a palimpsest of investigation and tentative endeavors we have been given glimpses - **more is hardly possible** - into the way Newton created his sciences ...”

Rupert Hall in “Review and Reminiscences”,  
The Foundations of Newtonian Scholarship, pg 201

In his introduction to Newton's Principia, the eminent Newtonian scholar I. B. Cohen asked:

Whatever happened to the work-sheets of the Principia? Do they still exist in some obscure private or public collection?

Was this particular set of manuscripts - alone of all the Newton papers - lost or mislaid, either when the Portsmouth Collection was still in Hurstbourne Castle or during the actual transfer

to the University Library in Cambridge? Did such work-sheets still exist among Newton's papers at the time of his death? Or were they lost or destroyed - either by chance or design - during Newton's own lifetime?

We may possibly never be certain of the answer to these questions.”

- I. B. Cohen, in “Introduction to Newton's Principia”
- II. (Cambridge University Press, Cambridge, 1971) p. 81.

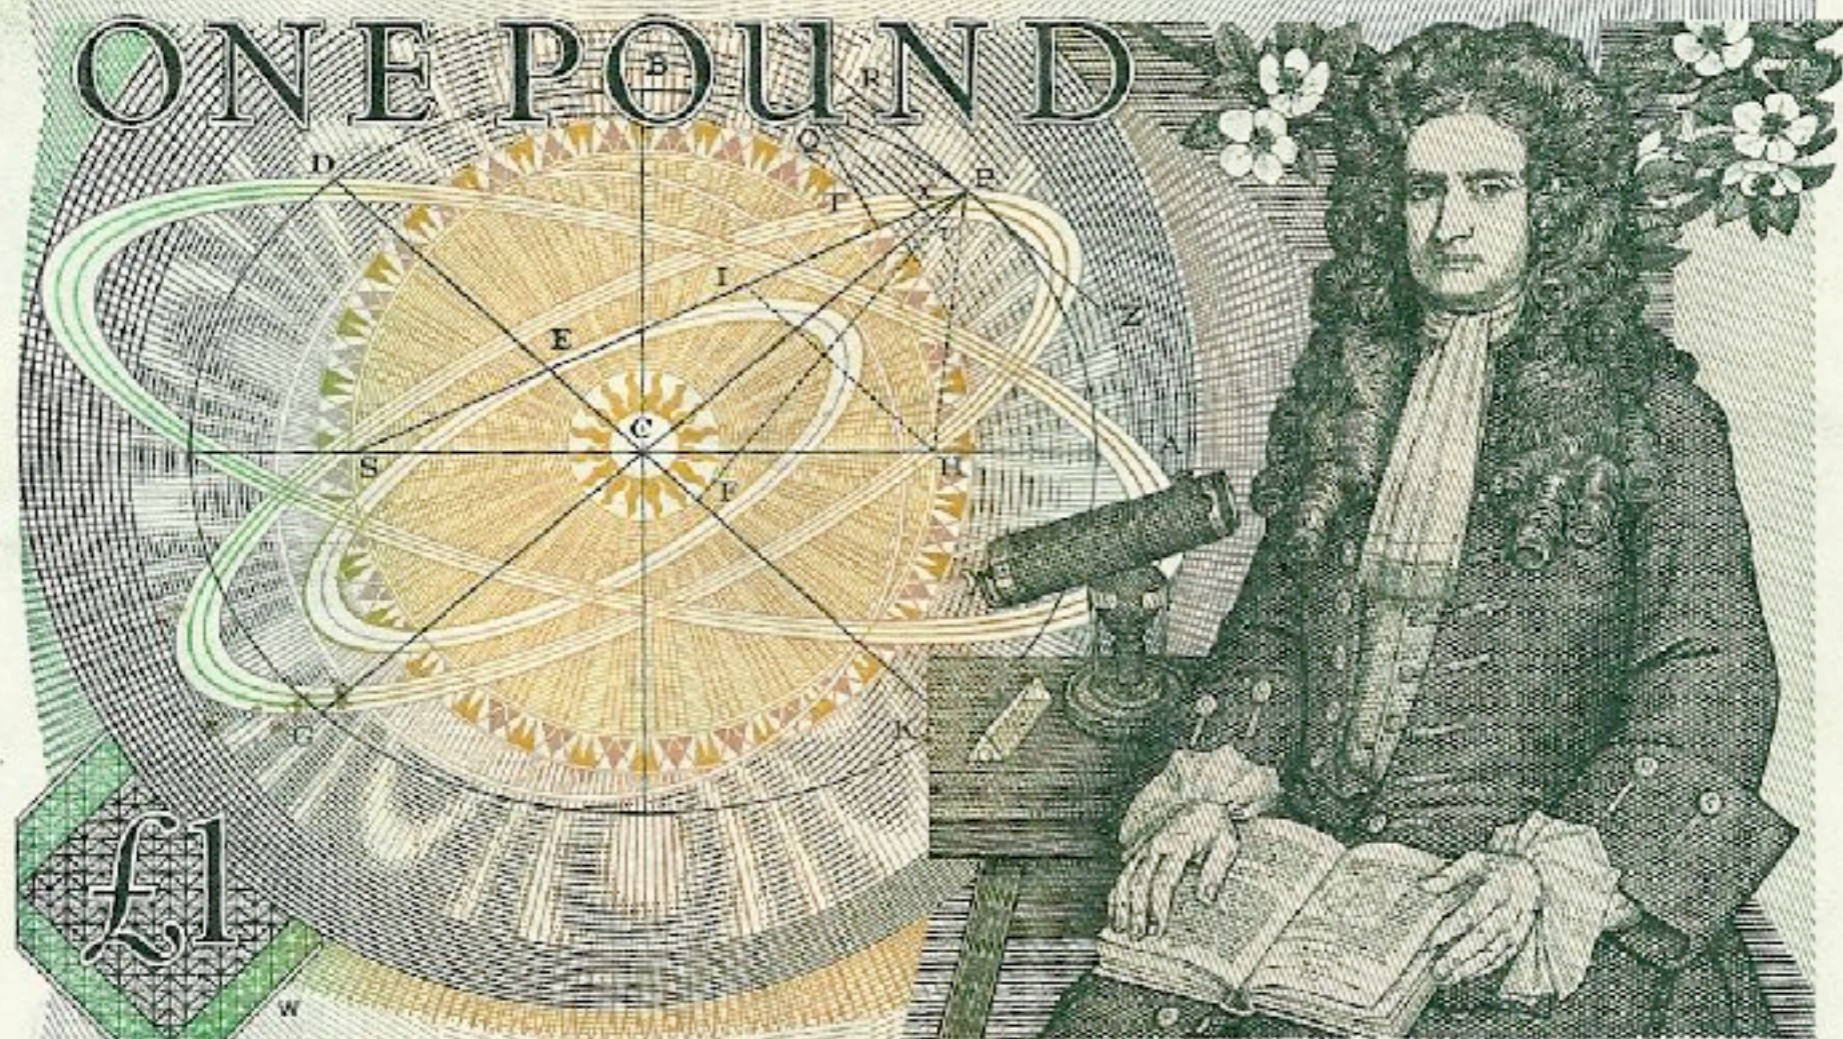

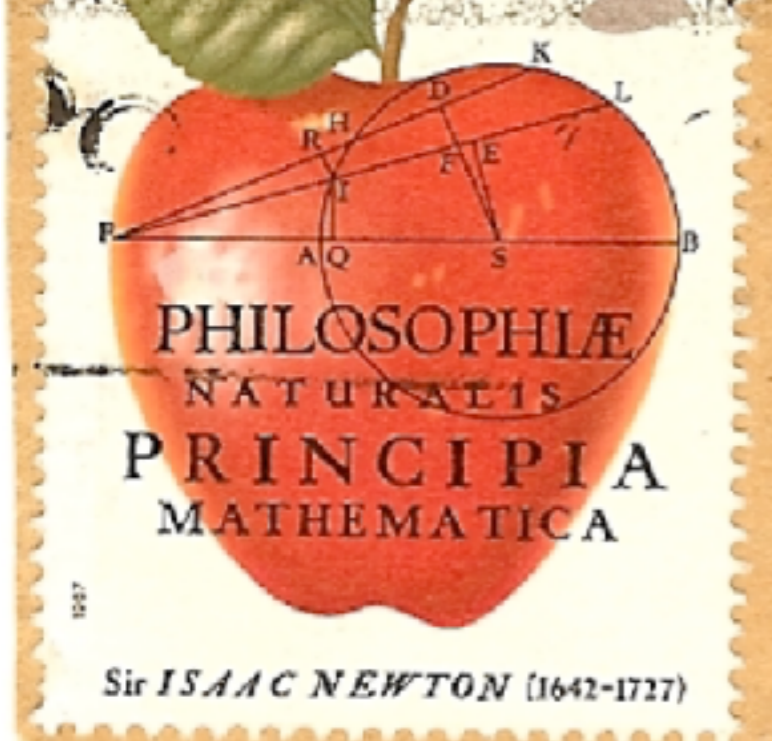

Certainly there can be no doubt that the peculiar geometrical form in which the exposition of the Principia is dressed up **bears no resemblance at all** to the mental processes by which Newton actually arrived at his conclusions”

J. Maynard Keynes in “Newton the Man” 1946

## **The apple story by John Conduitt**

While he was musing in a garden it came into his thought that the power of gravity (which brought an apple from a tree to the ground) was not limited to a certain distance from the earth but that this power must extend to much farther than was usually thought. Why not as high as the moon said he to himself and if so that must influence her motion and perhaps retain her in her orbit

THE NETHERLANDS

22 April 1996

Dear Mr Nauenberg,

Thank you for filling out a visitor comment form on 24 March 1996.

The caption about Kneller's portrait of Sir Isaac Newton was written by my predecessor, who has now left the Gallery, and so I can only presume what his intentions were in writing it. However I am sure that he did not intend to imply that Newton did not develop his law of gravity through a scientific process. Indeed, it is not certain that the incident with the apple ever happened, and I think that in writing that the laws of gravity were '*traditionally said to have been revealed to him*' when he saw an apple falling from a tree, my predecessor was simply intending to record a tradition that grew up about Newton's discovery after his death. On the other hand, Newton was, of course, a religious man as well as a scientist, and it may well be that he believed that there was a degree of religious revelation involved in stimulating his discoveries.

However, I agree that the caption is, perhaps, misleading in making Newton seem so passive in relation to his development of the law of gravity. I have amended the text, and I enclose a copy of the new caption. I hope that this meets with your approval.

Thank you for your interest in the Gallery. I hope that in spite of any annoyance caused by the Newton caption you enjoyed your visit.

Yours sincerely,

Catherine MacLeod

# LONDON'S LEONARDO

The Life and Work of  
ROBERT HOOKE

On November 24, 1679, Robert Hooke wrote to Newton :

“For my own part I shall take it as a great favour if you please to communicate by Letter your objections against any hypothesis or opinion of mine,

And particularly if you will let me know your thoughts of that of compounding the celestiall motion of the planetts of a direct motion by the tangents and an attractive motion toward the central body”

Hooke had elaborated his ideas in a short tract, published in 1674, entitled:

“An attempt to prove the motion of the Earth  
by observations”.

Hooke argued that attractive gravitational forces were universal. About terrestrial gravitation he wrote:

This propagated Pulse I take it to be the Cause of the descent  
of bodies towards the Earth

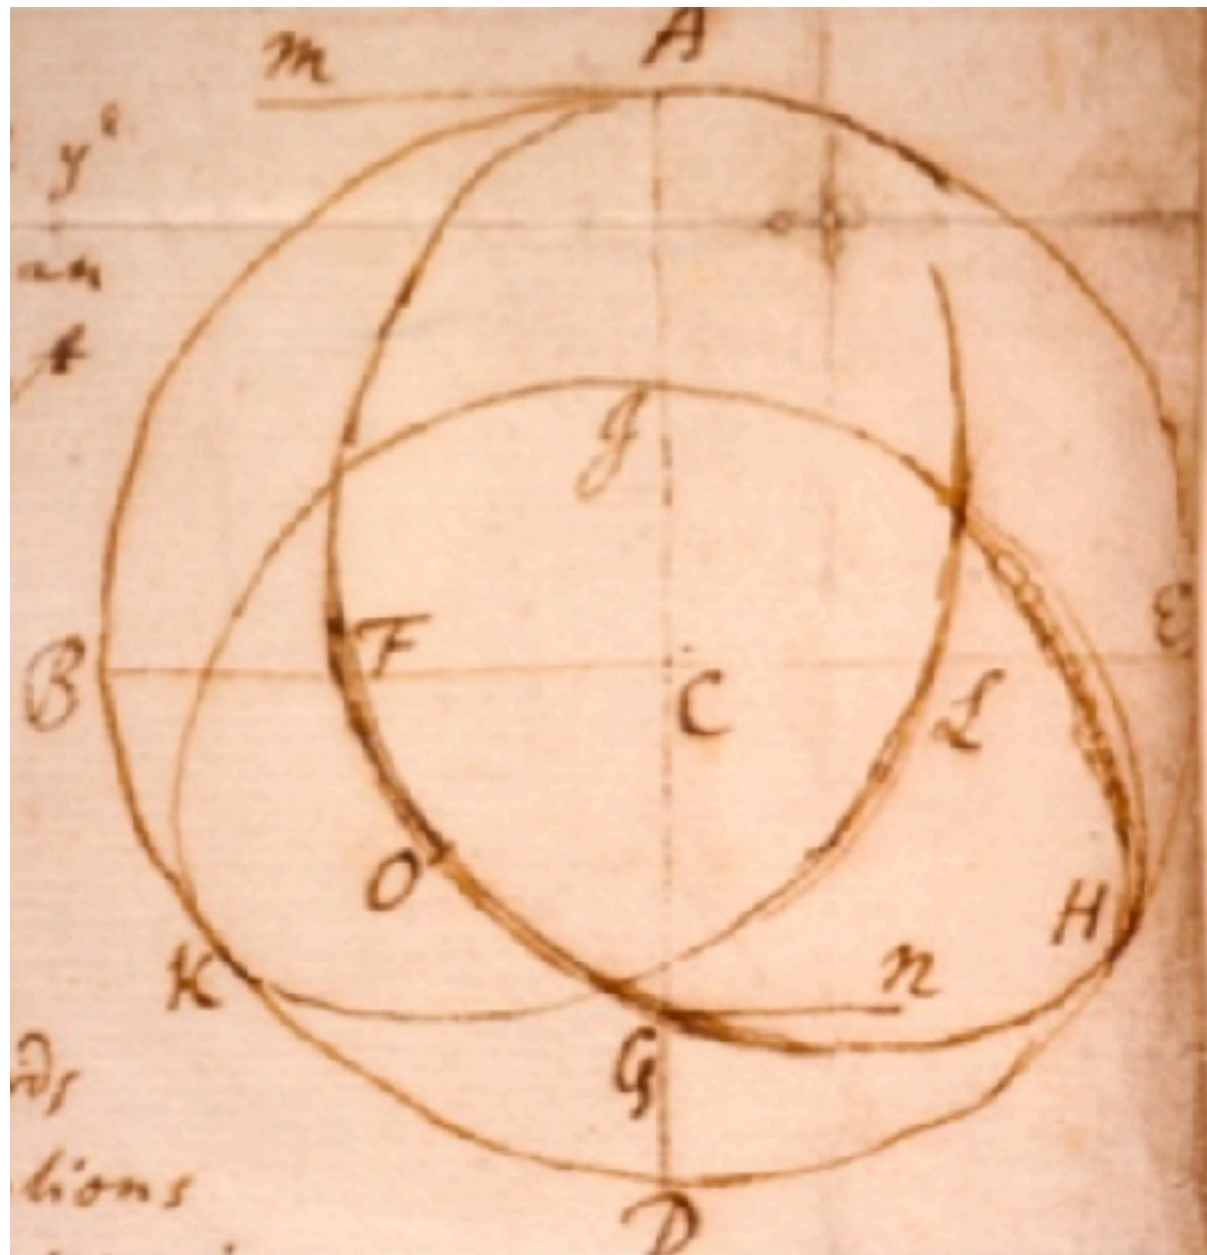

. . . Suppose for Instance there should be 1000 of these Pulses  
in a second of Time, then must the Grave body receive all those  
thousand impressions within the space of time of  
that Second, and a thousand more the next . . .”.

Newton's response to Hooke  
on Dec 24, 1679:

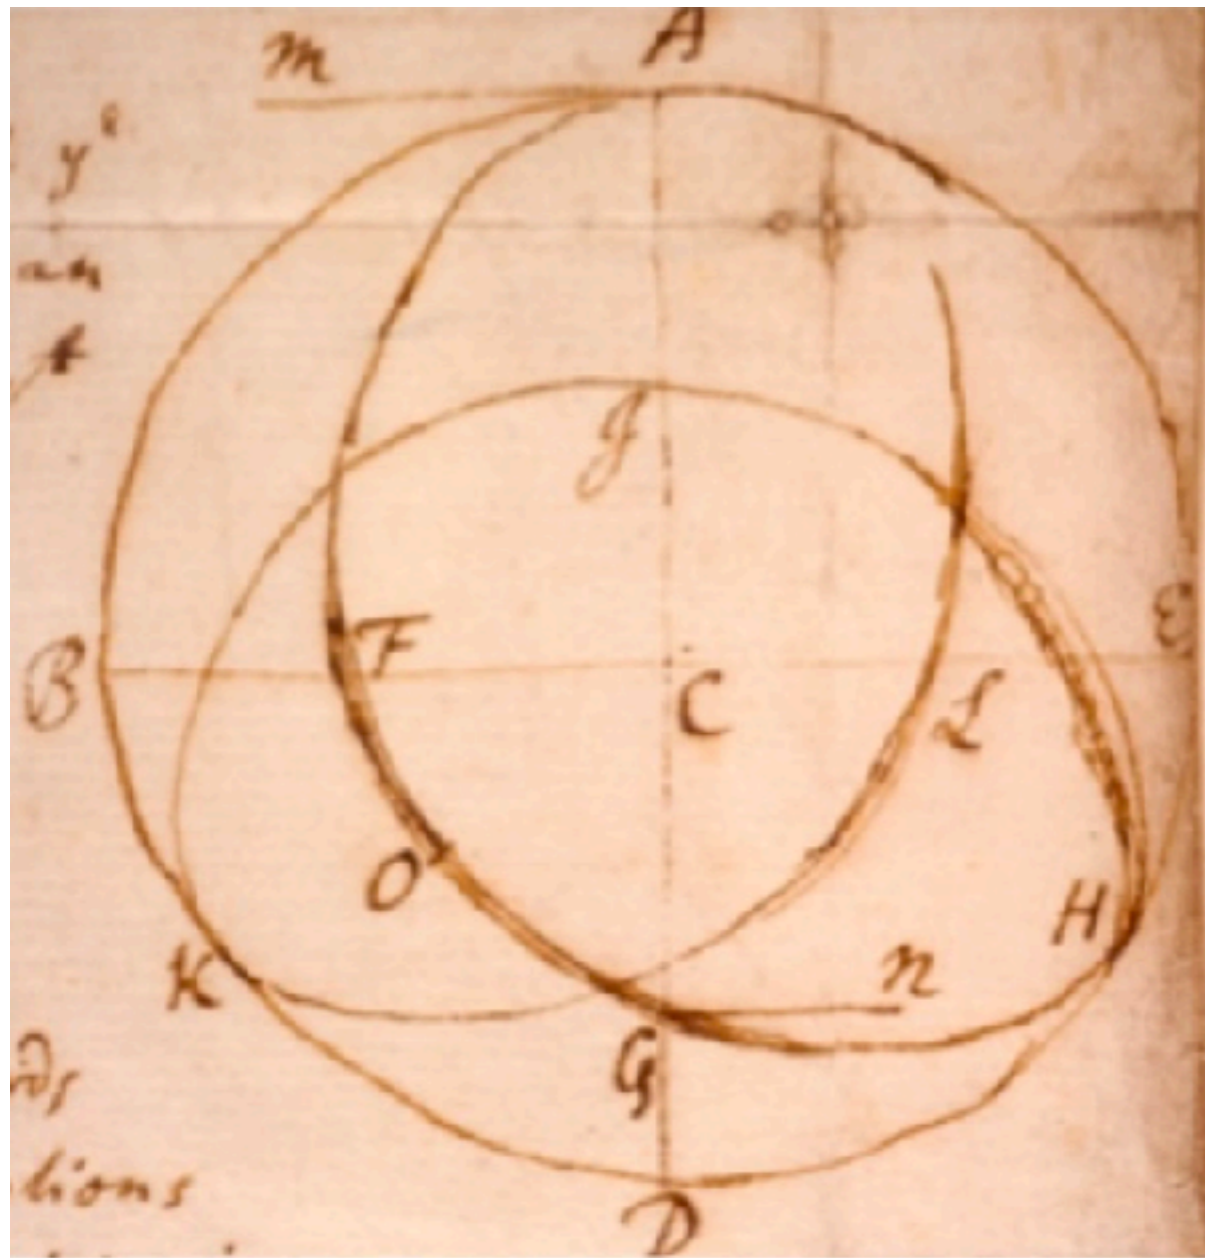

“Your accute letter having put  
me upon considering thus  
far the species of this curve,  
I might add something about  
its description by points  
quam proxime ...

Newton's letter to Halley  
on May 27, 1686

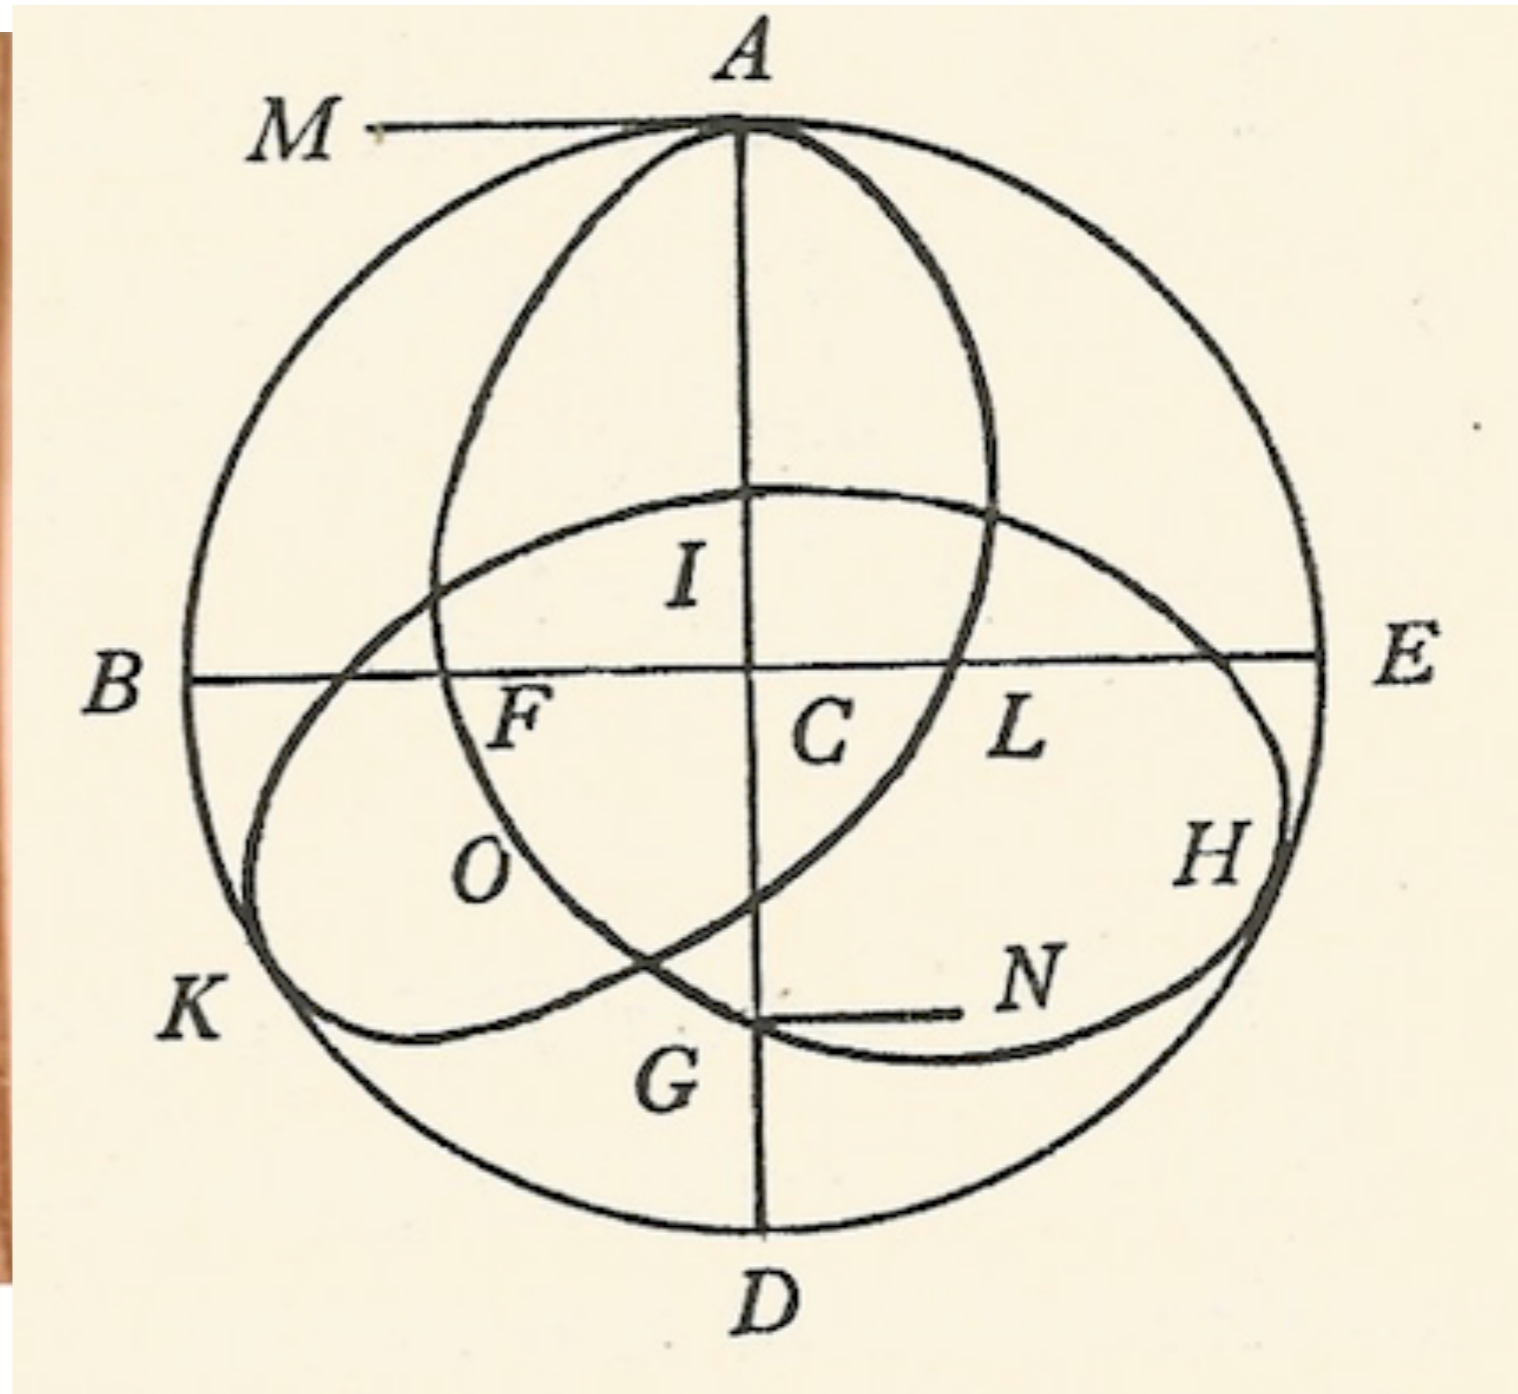

“I then took the **simplest case**  
for computation, which was that  
of Gravity uniform in a medium  
not Resisting”

Newton's drawing

Newton's 1679 diagram

Section of Newton's diagram  
based on local curvature

This letter contains among other mistakes  
an impossible picture of an orbit ...

V.I.Arnold in "Huygens & Barrow, Newton & Hooke

According to several accounts originating with Newton, on August 1684 Halley visited him and asked:

" what he thought the curve would be that would be described by planets supposing the force of attraction towards the Sun to be reciprocal to the square of the distance from it".

"Sir Isaac replied immediately that it would be an ellipses . . ." but when asked for his calculation he claimed that he couldn't find it.

Actually Newton could only answer the **converse** to Halley's question, if the curve is an ellipse, the central force is **an inverse square force**. It is unlikely that he could have answered Halley's original question

\* joy & amazement asked him how he knew it, why said he I have calculated it, whereupon Dr Halley, asked him for his calculation without any further delay, Dr Barrow looked among his papers but could not find it, but he promised him to return it, & then to send it him, Dr Barrow in order to make good his promise felt Dr Barrow again, but he could not come to that conclusion, yet he thought he had before examined with care, however he attempted a new way which tho' longer than the first, brought him again to his former conclusion, then he examined carefully what might be the reason why the calculation he had undertaken before did not prove right, & he found that having drawn an elliptic curve, with his own hand, he had drawn the two axes of the curve, instead of drawing two diameters somewhat inclined to one another; whereby he might have fixed his imagination to any two conjugate diameters, which was requisite he should do, that being perceived, he made both his calculations agree together.

After this Dr Halley was (I think) sent down to Cambridge by the Royal Society to prevent with Dr Barrow to print his discoveries which came into the Principia.

Dr Halley has since valued himself for having been the only one who produced this

# Hooke graphical calculation of the orbit for a force that depends linearly on the distance from the center

Newton claimed that “Dr. Hook  
could not perform that  
which he pretended to:  
let him give Demonstrations  
of it:  
I know he hath not Geometry  
enough to do it.”

# Letter of William Derham to Conduitt Esquire, July 18, 1733

Let  $ha$  represent the simple velocity <sup>tangent</sup> as before in the <sup>circle</sup> of <sup>motion</sup>, and  $ad$  <sup>the</sup> velocity imparted by gravity, make  $(d\beta)$  parallel & equal to  $(ac)$  then draw the  $dia$  gonals  $(ab)$ . the 2<sup>d</sup> pull of gravity shall meet the body at  $\beta$ . where the pull again meets it driving it towards the centre  $O$ . w<sup>th</sup> the velocity  $\beta\gamma$  which has the same ~~same~~ proportion to the radius  $\beta O$  that  $ad$  has to  $ao$ . make  $\beta\gamma = a\beta$  and make  $\gamma\epsilon$  equal & parallel to it then draw  $\beta\epsilon$ . now if the velocity to gravity had been as  $ha$  to  $da$  then the body had moved in a circle but because the velocity  $ha$  is less than in proportion to  $ad$  than it ought to make it move in a circle therefore the motion shall be in an ellipse. for as  $ad$  is to  $ad$  for  $\beta O$  to  $\beta\gamma$  so  $10$  to  $12$  and the same proportion that  $a\beta O$  has to  $a\beta O$  the same shall  $\beta\gamma O$  have to  $\beta\gamma O$ . the motion of this body therefore shall be polygonal in an ellipse. and shall describe equal areas in equal times

When the velocity and direction of the motion of a body dothally its Receding from the centre balance the recede by the Ray of Gravity then doth the body move in a circle if the gravity be to the centre of it. But if the Recede overbalance the recede it goeth further off: and the contrary if contrary, and the polygon becomes various according to the differing degrees of gravity at differing distances from the centre.

Hooke graphical calculation  
of the orbit for a force  
that depends linearly  
on the distance from the  
center

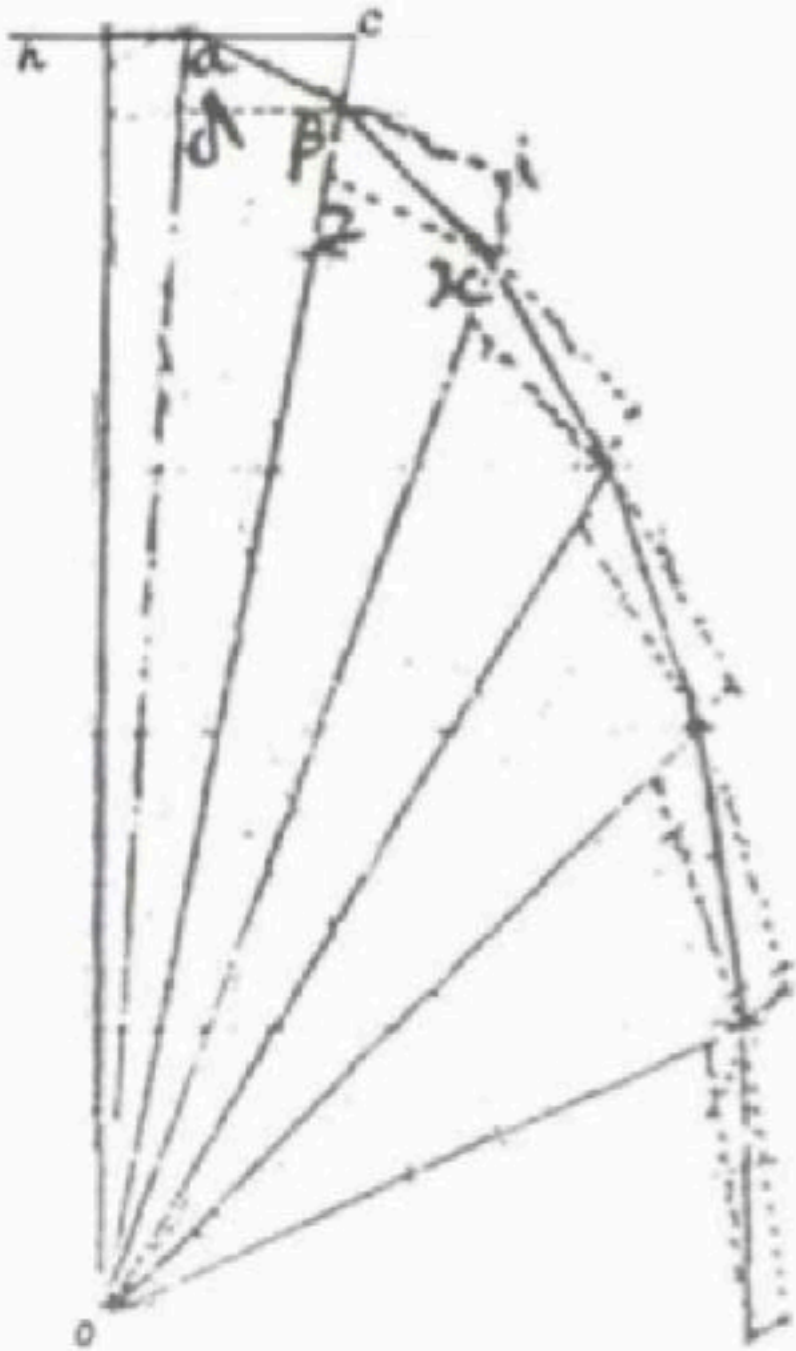

Newton claimed that "Dr. Hook  
could not perform that  
which he pretended to:  
let him give Demonstrations  
of it:

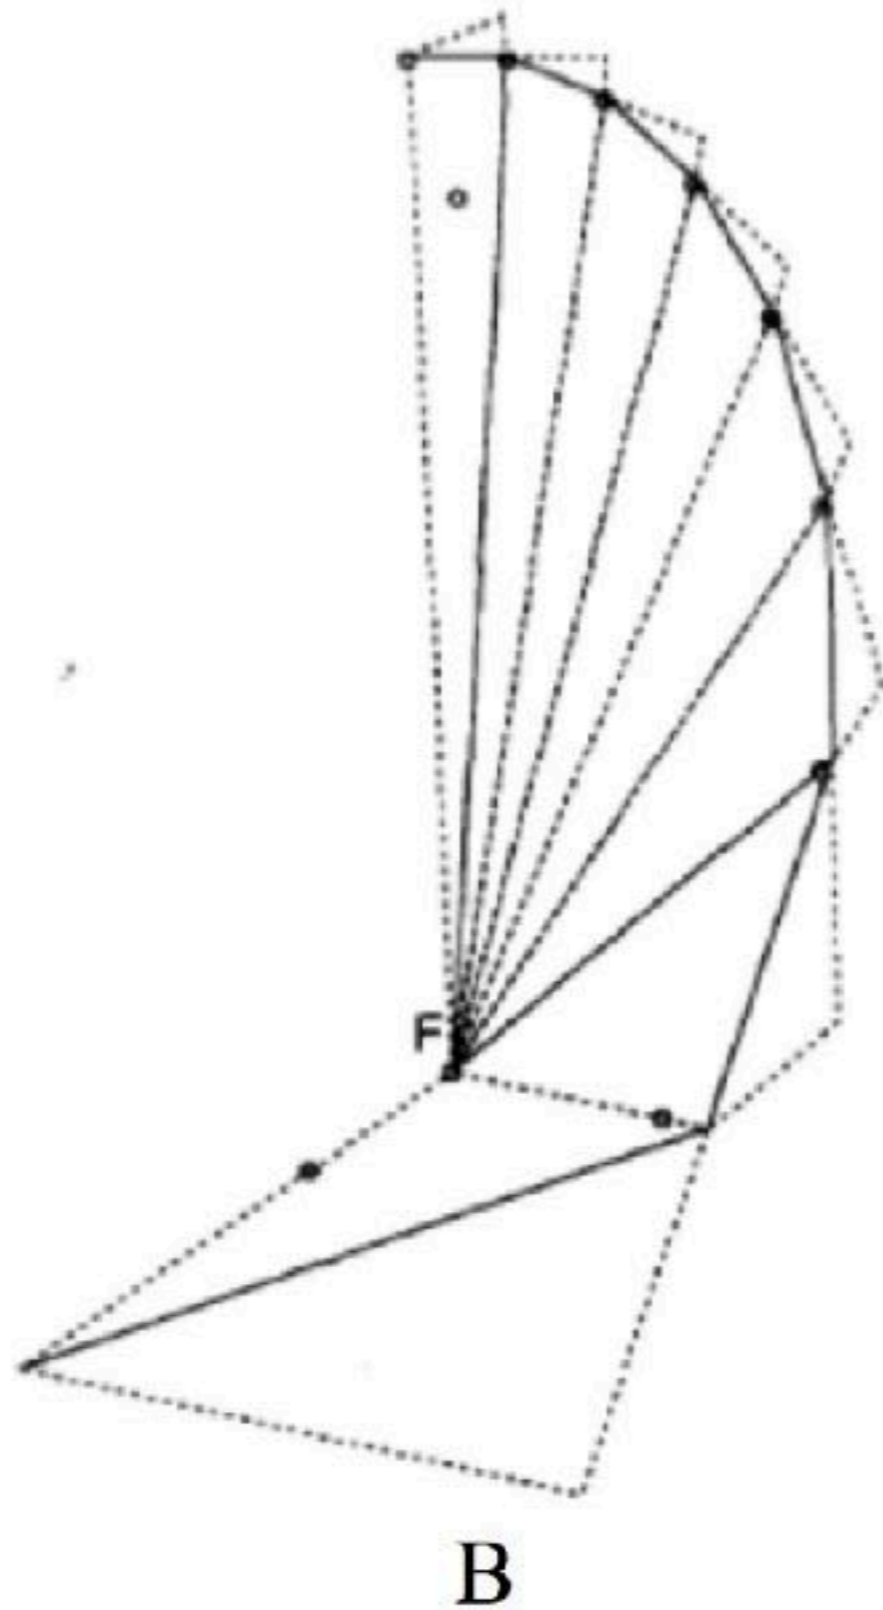

I know he hath not Geometry  
enough to do it."

Letter of William Derham  
to Conduitt Esquire, July 18, 1733

Hooke's graphical construction  
of an elliptic orbit for  
**central force** depending  
linearly on the distance  
from the center.

Drawn on Sept. 1685.

Graphical construction  
with **inverse square force**  
and Hooke's initial  
condition

In July 14, 1686, in a letter to Halley Newton admitted his indebtedness to Hooke. He wrote:

“This is true, that his Letters occasioned my finding the method of determining Figures which when I tried it in the Ellipsis ”

But then Newton equivocated claiming that:

“I threw the calculation by being upon other studies & so it rested for about 5 years till upon your request I sought for yt paper, & not finding it did it again and reduced it into ye Proposition shown you for Mr. Paget . . . .”

In November, 1684, Newton sent to the Royal Society a treatise of 9 pages “On the Motion of Bodies in an Orbit”, that constituted the first draft of the Principia

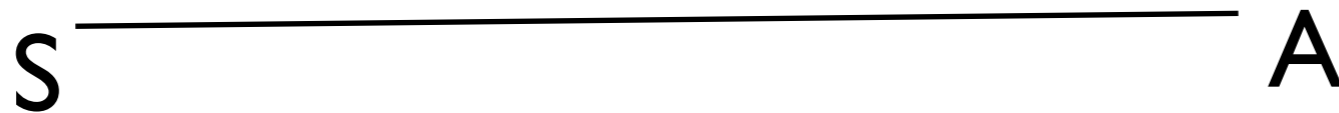

During his conflict with Leibniz on the development  
of the Calculus, Newton wrote

“In the end of the year 1679 in answer to a letter from Dr.Hook then secretary of the R.S. . . I wrote that Whereupon I computed what would be the Orb described by the Planets, for I had found before by the sesquialterate proportion of the tempora periodica of the Planets with respect to their distances from the Sun, that the forces which kept them in their Orbs about the Sun were as the squares of their mean distances from the Sun reciprocally, & I found now that whatsoever was the law of the forces which kept the planets in their Orbs the areas described by a Radius drawn from them to the Sun would be proportional to the times in which they were described. And by the help of these Propositions I found that their Orbs would be such Ellipses as Kepler had described.

MS. Add 3958 b fol. 101

# Graphical Construction of orbit for constant central impulses, based on Hooke's physical concept and Newton's mathematical implementation.

Let  $S$  be the center of force  
and  $A$  the initial position of a body

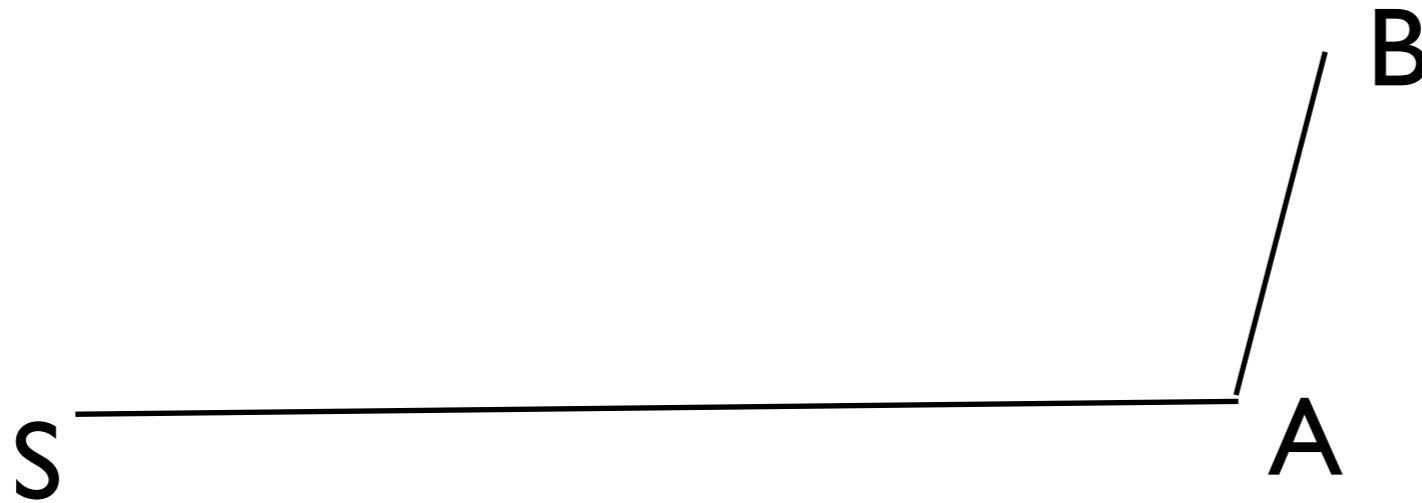

Draw the initial displacement AB

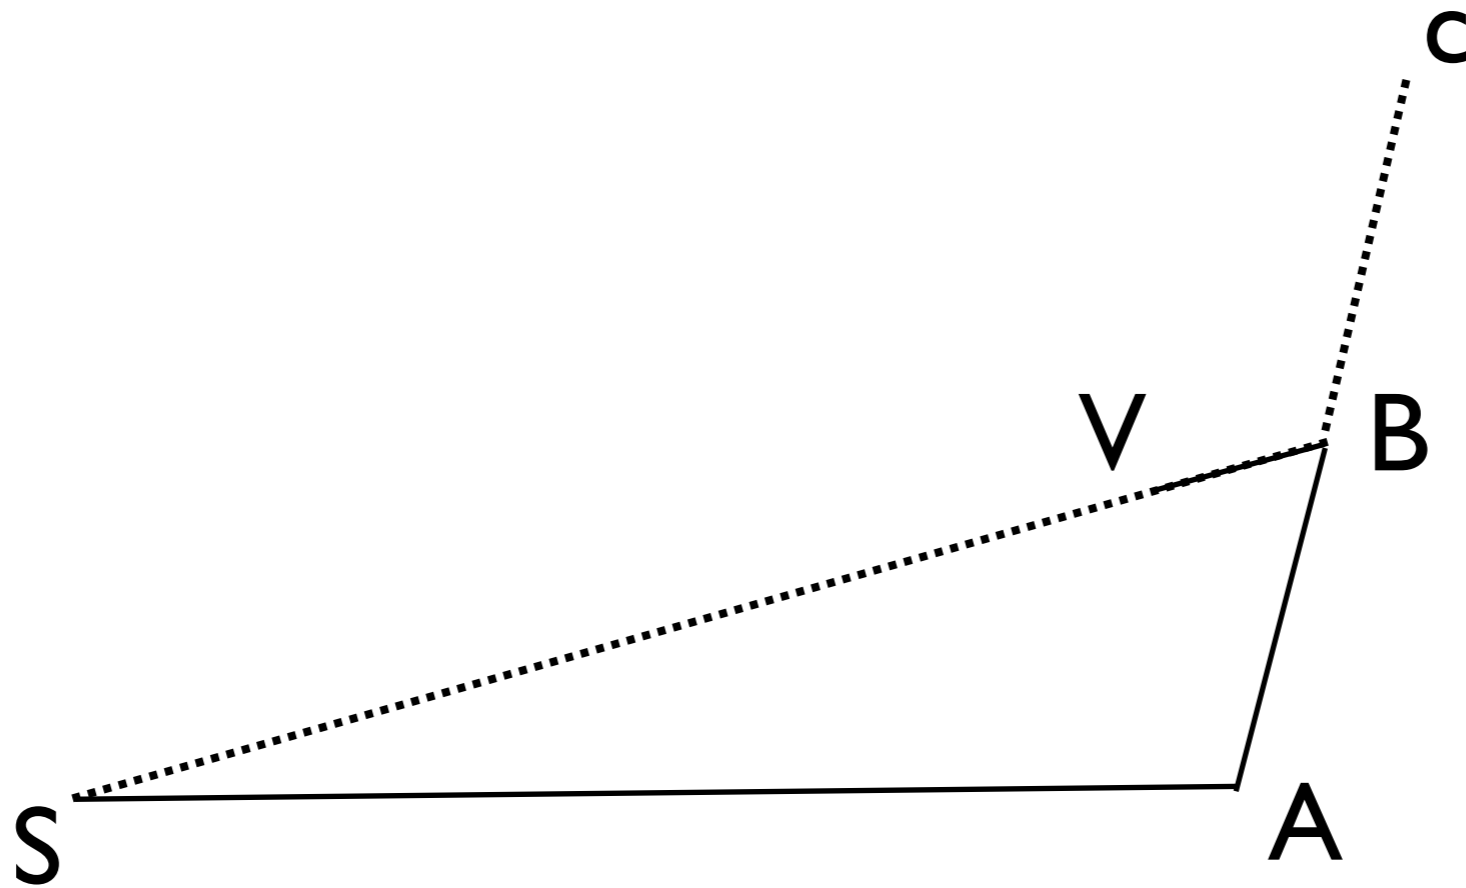

were  $AB = v\delta t$

$v$  = initial velocity

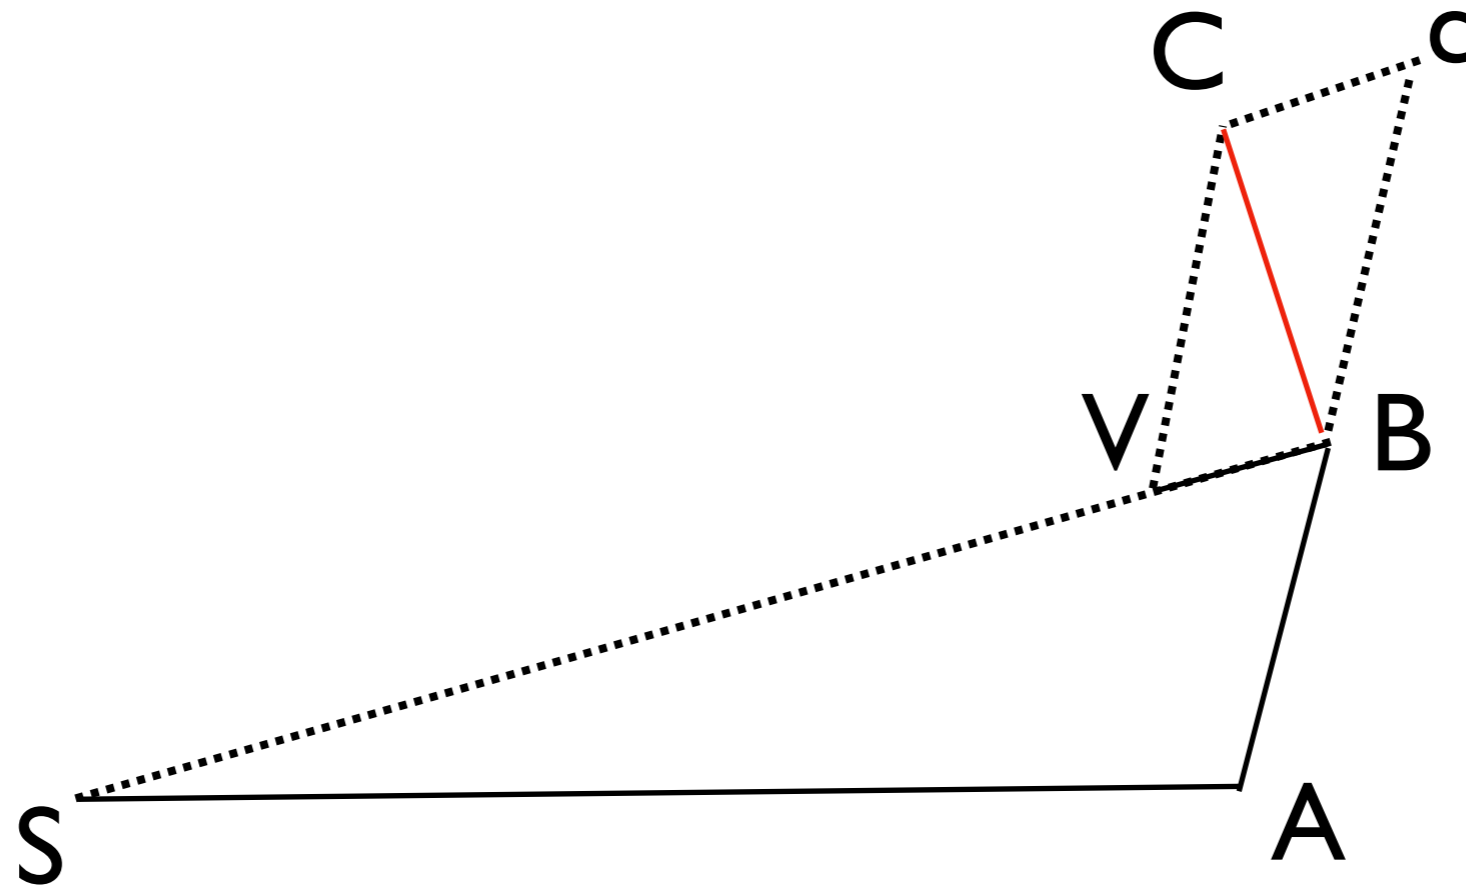

$\delta t$  = time interval between  
periodic impulses

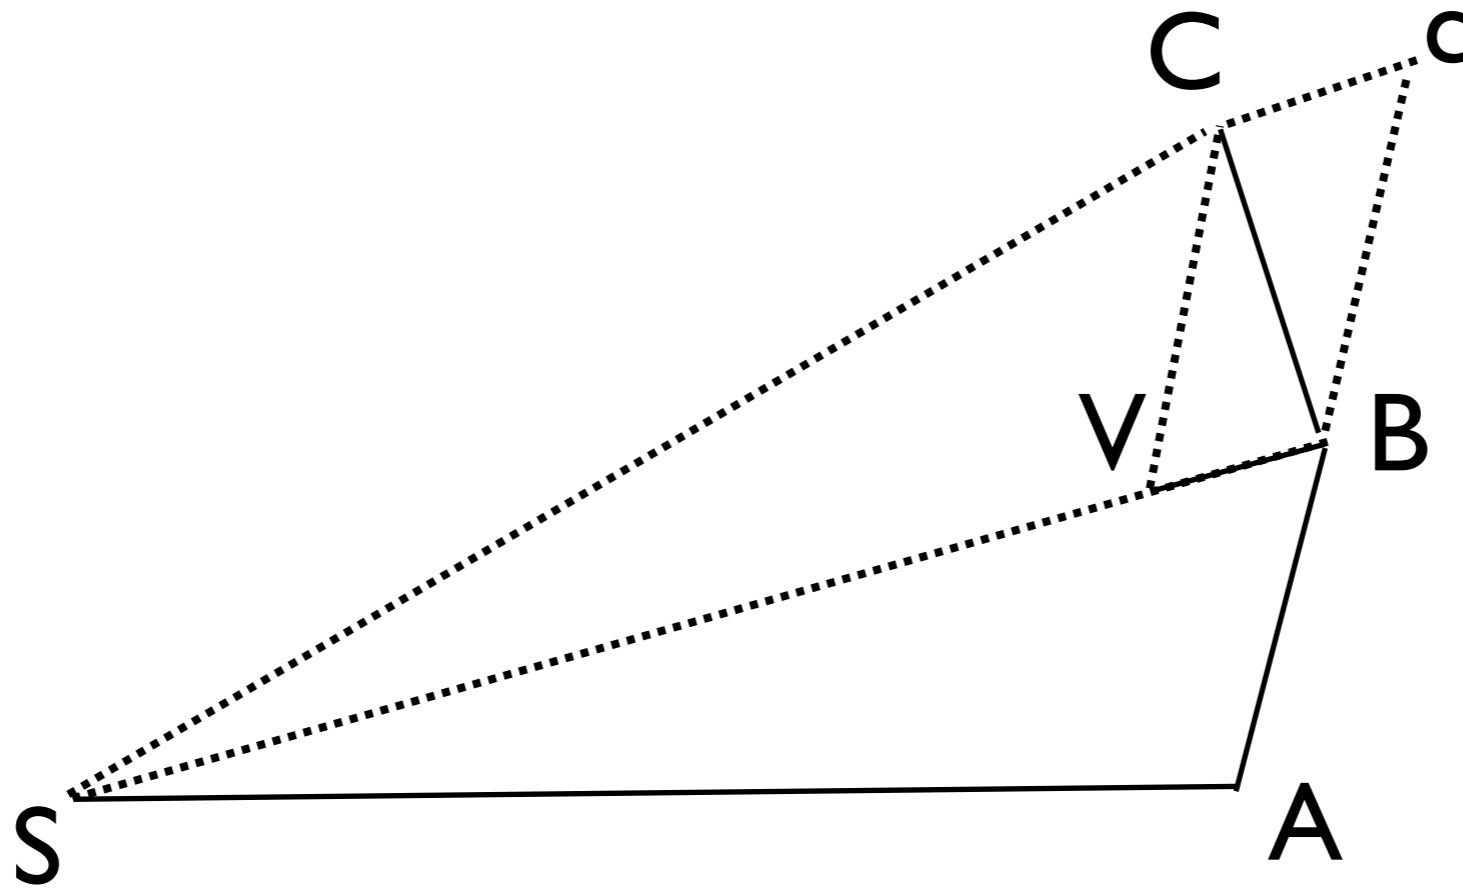

To obtain the next point  
draw the extension  $Bc=AB$ ,  
and the impulse  $BV$  at  $B$   
directed along  $SB$

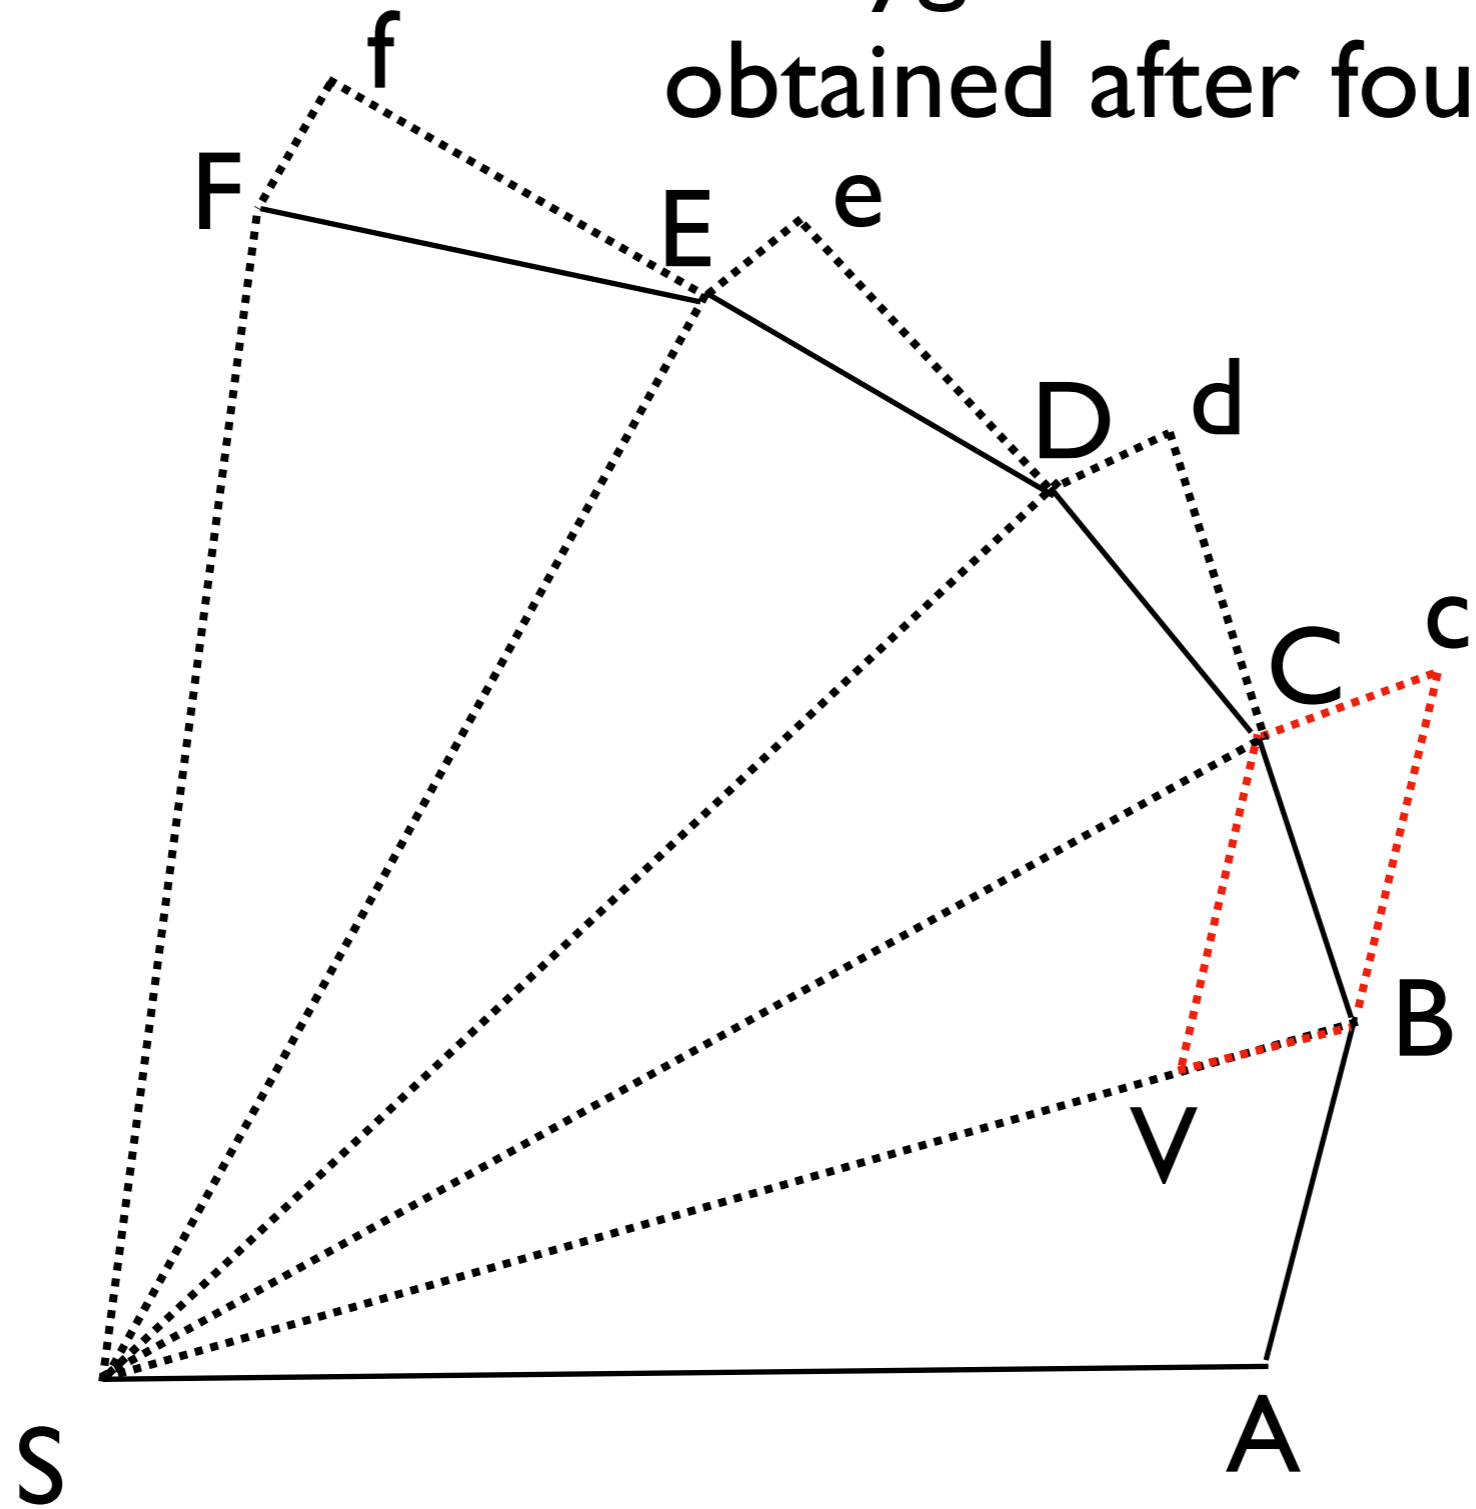

Obtain the next point C by Newton's parallelogram construction to add velocities **vectorially**:  
draw VC parallel and equal to extension Bc  
or draw Cc parallel and equal to impulse VB.  
Then BC is the displacement after the impulse at B

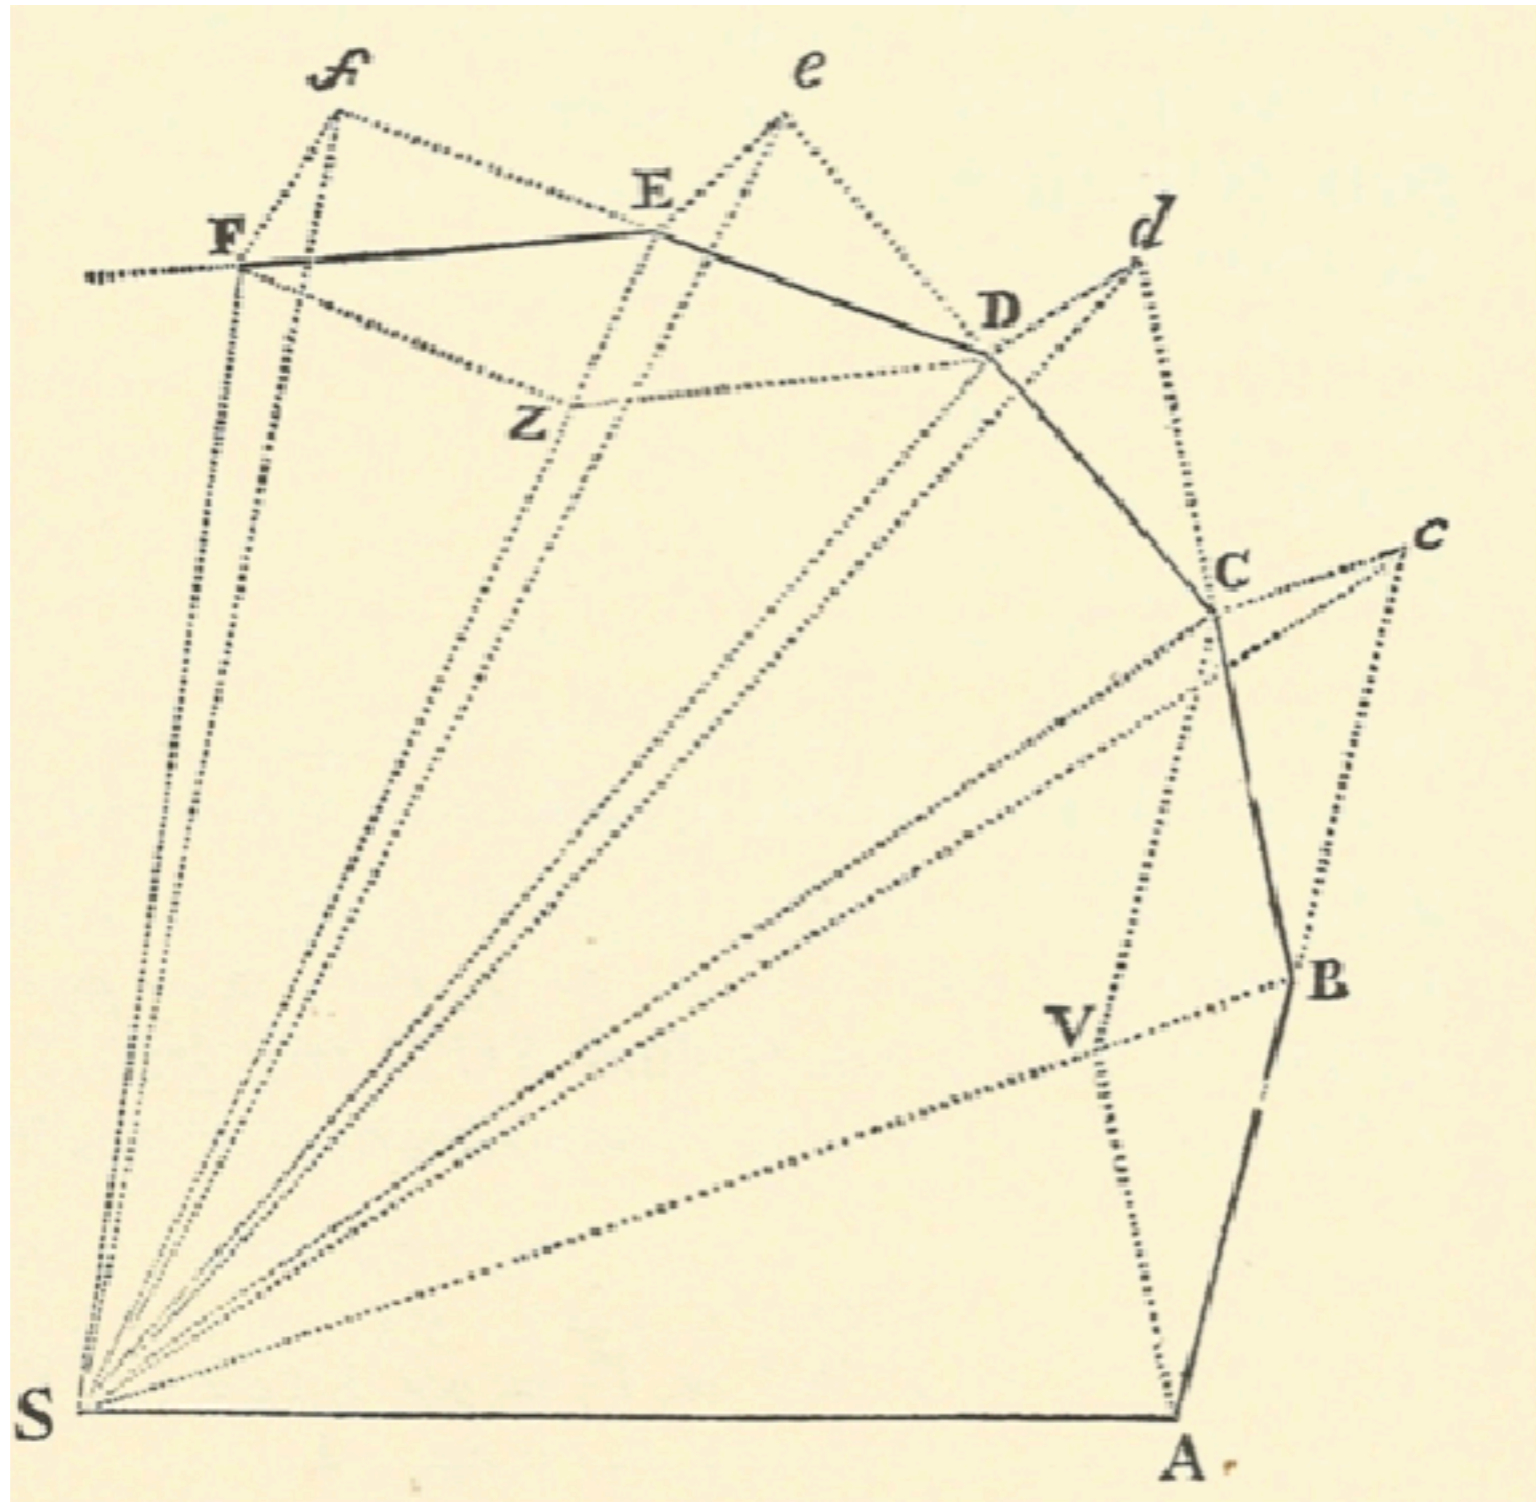

Join S to C and repeat this graphical construction for successive impulses at periodic intervals  $\delta t$

Polygonal orbit ABCDEF  
obtained after four impulses

# Newton's diagram for Proposition I in Principia, Book I

# Analytic form of Newton's graphical construction

The velocity  $\vec{v}(i)$  before the  $i$ th impulse is

$$(1) \quad \vec{v}(i) = \frac{\vec{r}(i) - \vec{r}(i-1)}{\delta t},$$

and after the  $i$ th impulse

$$(2) \quad \vec{v}(i+1) = \vec{v}(i) + \vec{f}(i)\delta t,$$

where  $\delta t$  is the periodic time interval between impulses,

$$(3) \quad \vec{f}(i) = \frac{\vec{h}(i)}{\delta^2 t},$$

$\vec{h}(i)$  is the magnitude of the impulse, and  $\vec{f}(i)$  is the corresponding force.

According to Eq. 1,

$$(4) \quad \vec{r}(i+1) = \vec{r}(i) + \vec{v}(i+1)\delta t,$$

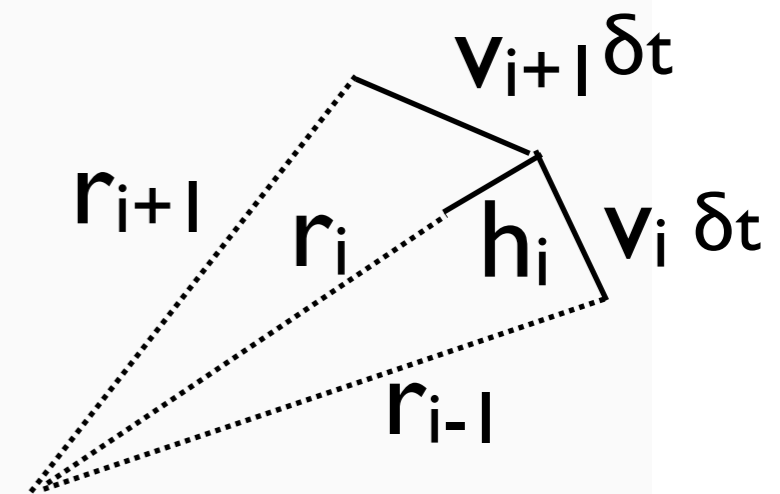

and Eqs. 2 and 4 are the analytic form of Newton's graphical equations of motion.

These two equations are symplectic (area preserving), and have been rediscovered several times in the past.

In the limit  $\delta t \rightarrow 0$ , Eq. 2 is the well known equation of classical mechanics

$$(5) \quad \vec{f}(t) = m\vec{a}(t),$$

where  $\vec{a}(t) = \delta\vec{v}/\delta t$  and  $m = 1$ .

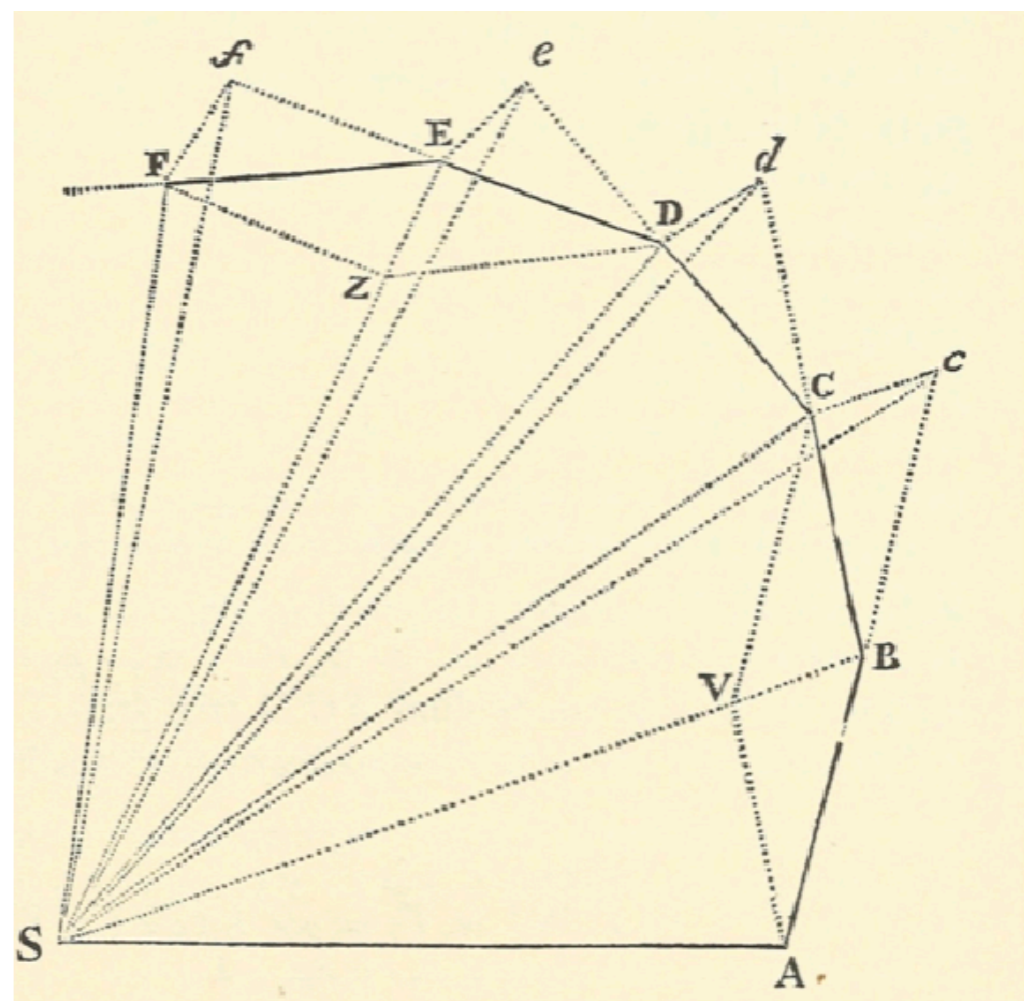

some other force.  
Hyp. 2. The alteration of motion is ever proportional to the force by which it is altered.  
If two motions are made in different lines, if these lines be taken

A diagram of a parallelogram with vertices labeled A, B, C, and D. Vertex A is at the bottom-left, B is at the top-left, C is at the bottom-right, and D is at the top-right. A diagonal line segment connects vertex A to vertex C.

Prop. 1.  
If a body move in vacuo & be continually attracted towards an immovable center, it shall constantly move in one & the same plane, & in that plane describe equal areas in equal times.

## Conversation between Laplace and Napoleon at a reception in 1802

Napoleon: Newton spoke of God in his book.  
I perused yours but failed to find his name  
even once

Laplace: I had no need for that  
hypothesis

Knowledge of the method that has  
guided a man of genius is no less  
useful to the progress of science  
and to his glory than his discoveries;  
the method is often the most  
interesting part”.

The background of the cover is a dark blue field filled with a complex geometric diagram. This diagram consists of numerous intersecting arcs and straight lines, creating a web of geometric shapes. Various letters are placed at key points of intersection and along the lines: 'T' appears in the upper left and lower right; 'a' is at the top left and bottom right; 'H' is in the center; 'D', 'C', 'B', 'E', 'V', 'N', 'S', 'R', and 'b' are scattered throughout the lower half. The overall style is reminiscent of the geometric proofs found in Newton's 'Principia'.
