The Problem of Scales in Quantitative Viral Ecology:

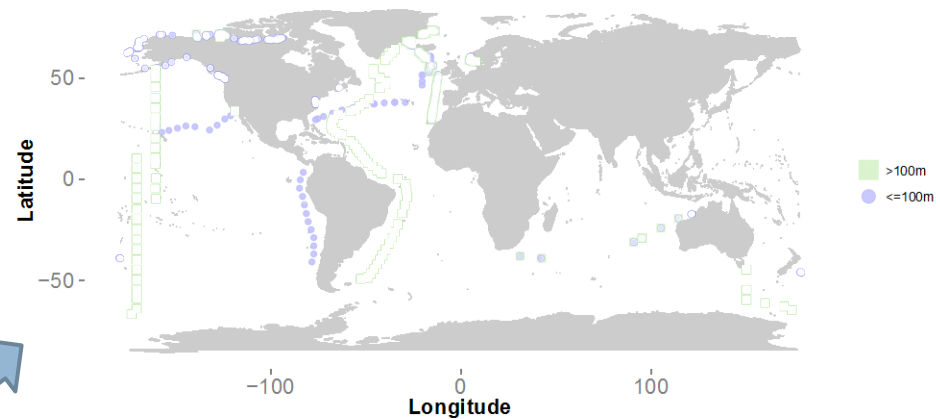

Linking Mechanism to Pattern

Virus-host interactions modify the fate of cells on time scales similar to division times...

Infection and lysis leads to Lotka-Volterra like dynamics at the population scale...

Which scale-up to massive ecosystem effects when integrated over the global oceans.

See: [“Quantitative Viral Ecology: Dynamics of Viruses and Their Microbial Hosts”](#) (2015). J.S. Weitz,

It wasn't always this way...

Today:

What do we know and what can we learn about marine virus effects on community and ecosystem processes over

Time (part 1)

&

Space (part 2)

Time (Part 1):

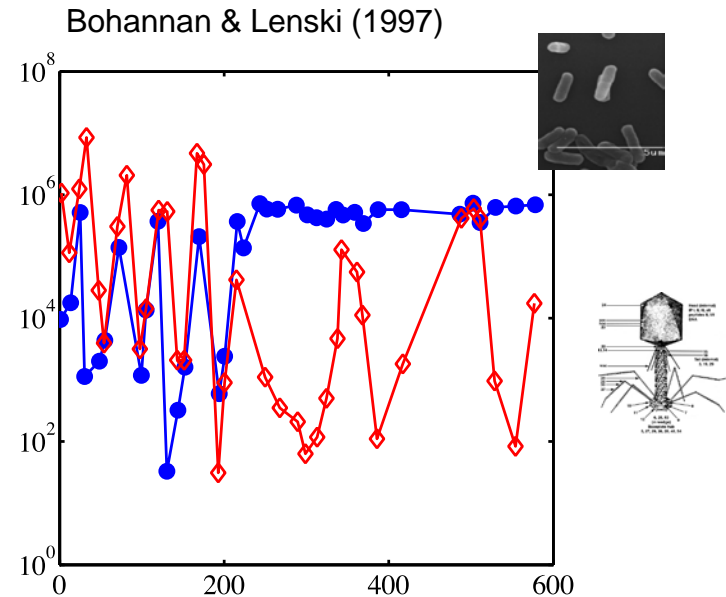

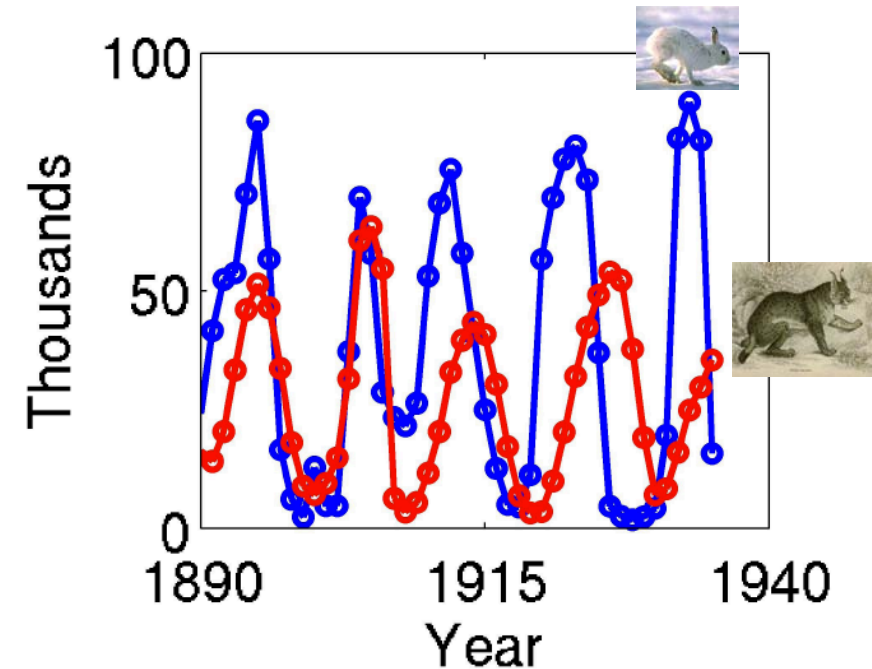

Quantifying the nonlinear
dynamics of virus-microbe
communities

what we know

Canonical concept: virus-microbe interactions lead to “Lotka-Volterra” dynamics

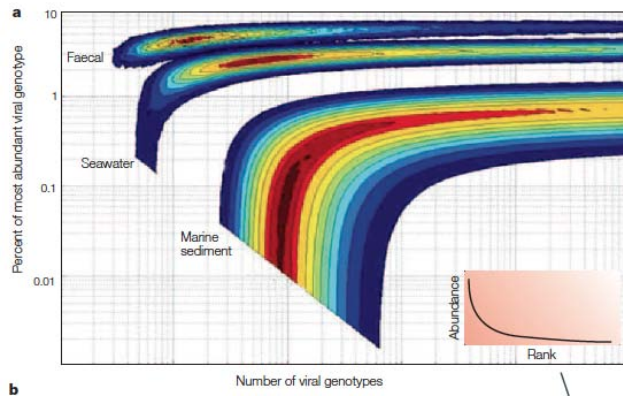

Canonical concept: virus-microbe interactions lead to “Lotka-Volterra” dynamics

However, natural virus communities are highly diverse

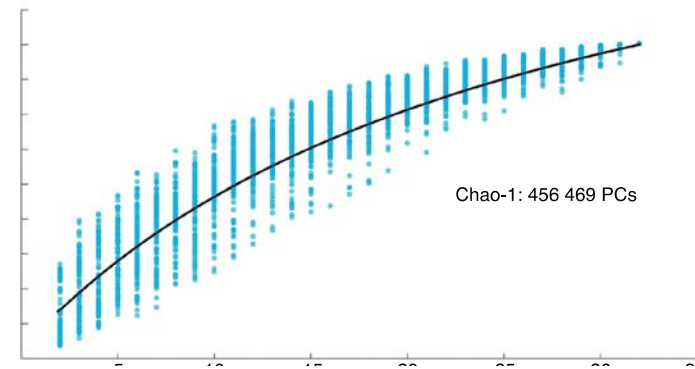

15

The marine sediment sample contained between 10,000 and 1 million viral genotypes.

- Rohwer and Edwards, *Nature* 2005.

On estimation problems see:
Haegeman, et al. *ISME J* 2013

It seems likely that viral sequence space, while large, is unlikely to approach the two billion genes estimated from 14 genomes a decade ago.

- Ignacio-Espinoza, Solonenko & Sullivan, *Curr Opin Virology*, 2013

How to characterize who infects whom...

- Collect bacteria and phages for host-phage typing studies, from the environment, or from an experiment.
- Use spot assays to see “who infects whom”

An example dataset: Miklic A. and Rogelj I. (2003)

Table 1 Host specificity of phages for eighteen isolated *Lactococcus lactis* strains

Host

Virus

Approach: use dynamic models of phage-bacteria communities to predict potential modes of coexistence

26

$$\begin{aligned}
 \text{Change of density of host } i & \quad \overbrace{\frac{dH_i}{dt}}^{\text{Host growth and competition}} = r_i H_i \left(1 - \frac{\sum_j H_j}{K} \right) - \overbrace{\sum_j M_{ij} \phi_j H_i V_j}^{\text{Viral lysis}}, \\
 \text{Change of density of virus } j & \quad \overbrace{\frac{dV_j}{dt}}^{\text{Virion release}} = \sum_i M_{ij} \phi_j \beta_j H_i V_j - \overbrace{m_j V_j}^{\text{Viral decay}},
 \end{aligned}$$

Infection Network

Similar, except that cross-infection is structured...

Initial results:

dynamics can differ given the same infection network

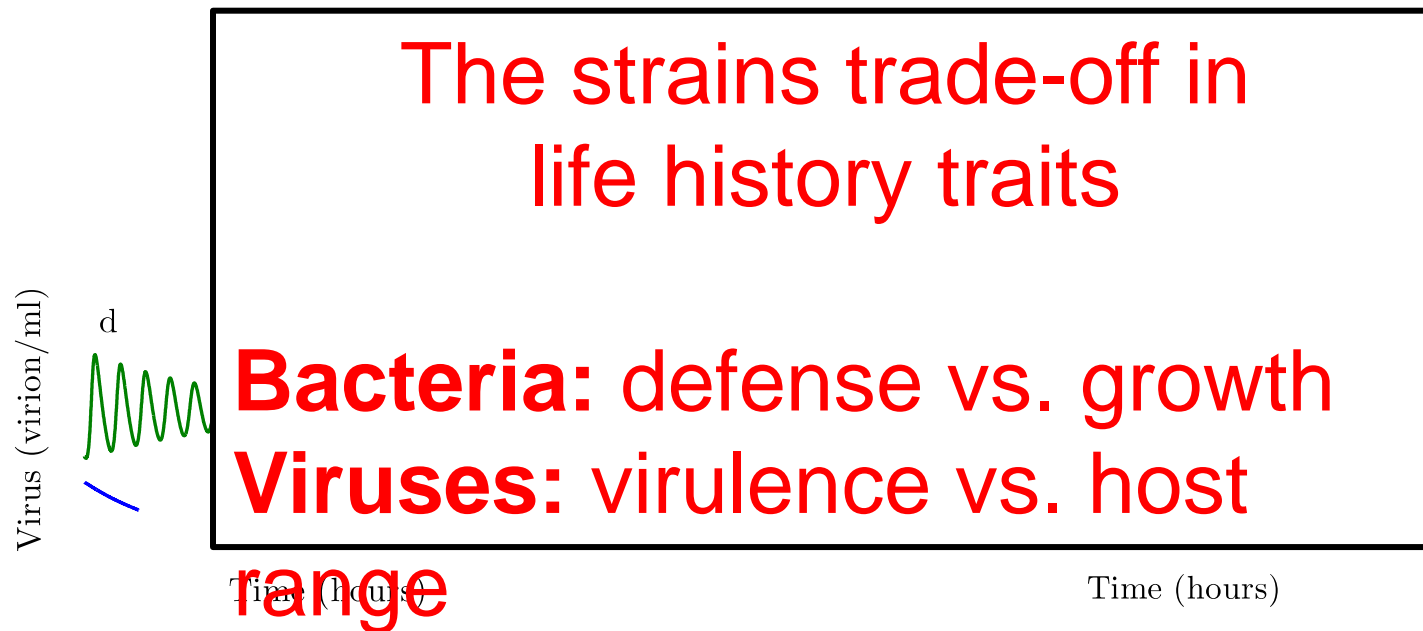

27

Community A:

1 virus and 1 host coexist

Community B:

2 viruses and 2 hosts coexist

Both communities have 2 viruses, 2 hosts, and a nested network...

Coexistence occurs via a stable fixed point or oscillations when trade-offs are satisfied

Is there evidence for such trade-offs?

Trade-offs linking life history rates and infection ranges

Genomic island variability facilitates *Prochlorococcus*–virus coexistence

Sarit Avrami¹, Omri Wurtzel², Itai Sharon¹, Rotem Sorek² & Debbie Lindell¹ [doi:10.1038/nature10172](https://doi.org/10.1038/nature10172)

DOI: 10.1534/genetics.105.051136

Viral tradeoff:
fitness vs. host range
(sometimes)

But are nested infection networks common at larger, marine scales?

Moebus and Nattkemper (Helgol Meeresunters, 1981)

- Bacteria and phages collected at 48 different stations in the Atlantic Ocean.

Fig. 1: *Source:* (7900 × 6618 pixels) We scanned the original source of the study. Rows represents bacteria and columns phage. A filled circle represents a strong interaction while an unfilled circle a weak interaction.

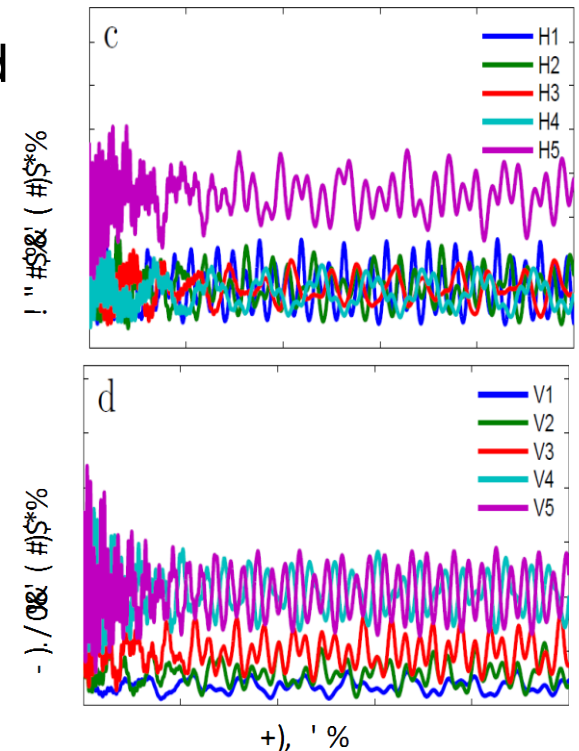

Phage-host networks are modular at large-scales (and nested within a “module”)

31

Summary thus far...

- Tradeoffs facilitate coexistence of viruses and their hosts.
- Abundance and resistance are not necessarily correlated.
- Nestedness and tradeoffs do not need to be “perfect” for coexistence
- Modular networks can also give rise to persistent diversity.

1996 – 2012 – More Numbers

Viruses and large-scale patterns in the global oceans

49

We find substantial variation in the virus to microbial cell ratio, approximately 2-orders of magnitude.

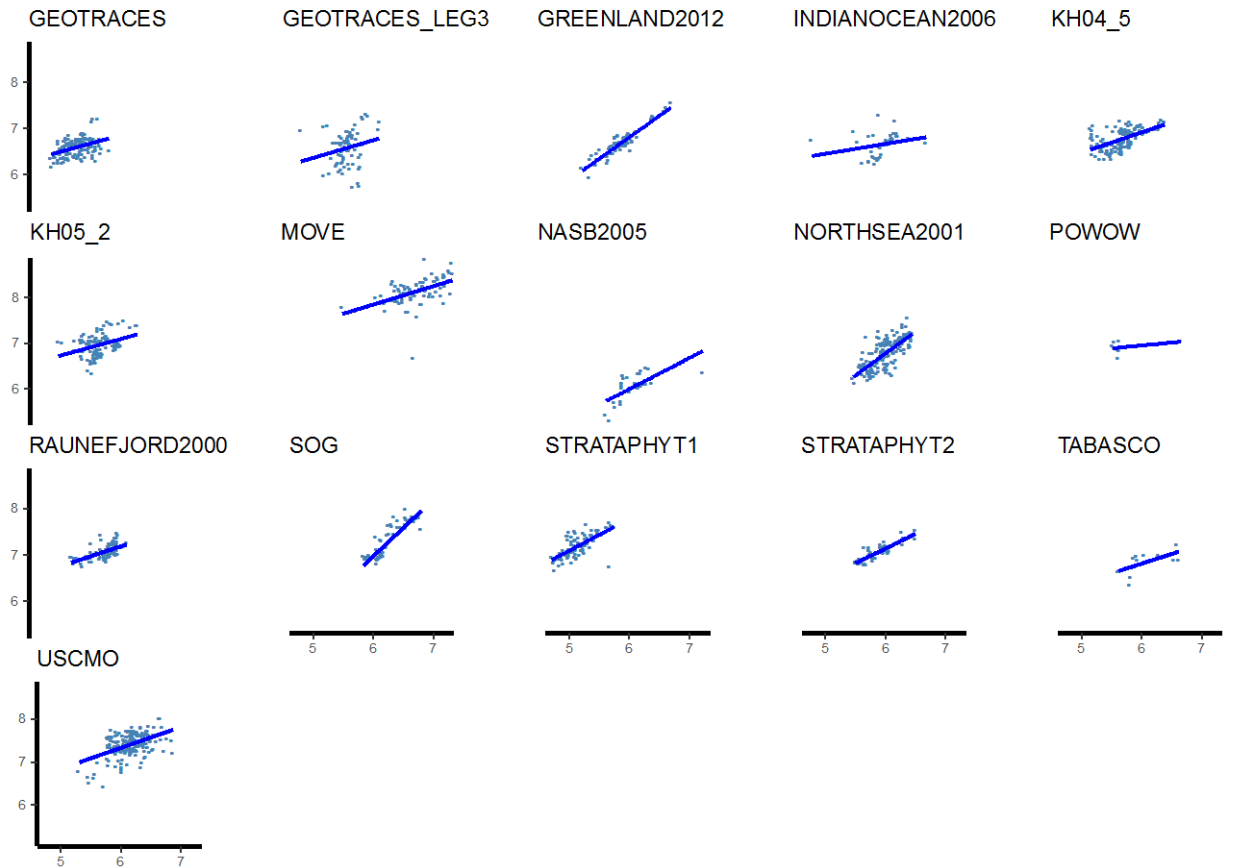

The variation in virus-to-microbe abundances is poorly described by a 10:1 model.

Instead, large variations are typical!

How do emergent virus-to-microbe relationships vary in distinct ocean sampling regimes?

1. Analyze each marine survey separately.
2. Assess the relationship between virus and microbial cell abundances.

How do emergent virus-to-microbe relationships vary in distinct ocean sampling regimes?

1. Analyze each marine survey separately.
2. Assess the relationship between virus and microbial cell abundances.
3. Power-law relationships tend to have scaling exponents < 1
4. In general, the virus-to-microbe ratio *decreases* with increasing microbial cell, rather than remaining fixed.

See related work in Knowles et al. Nature (2016) & Parikka et al. Biol. Reviews (2016)

A maximum likelihood approach: applied to the global oceans virus-microbe dataset

B. Cael Barry

Stephen Becker

Constant variance model –
the spread in virus densities is
independent of microbial
densities

AIC = 4682

Variable variance model – the
spread in virus densities
increases with microbial
densities

AIC = 4130 (better support)

Challenges for the field:

1. Fewer viruses per microbe as microbes increase in abundance.
2. Virus-microbe profiles of surface environments are more dissimilar than deep environments.

Space (Part 2):

Lysogeny

“Piggyback the Winner (PtW)”

Knowles et al., Nature, 2016

Piggyback-the-Winner: Concepts and Critiques

Piggyback-the-winner: Lysis suppressed and lysogeny enhanced at high productivity/densities, thereby causing decreases in VMR.

Piggyback-the-Winner: Concepts and Critiques

Piggyback-the-winner: Lysis suppressed and lysogeny enhanced at high productivity/densities, thereby causing decreases in VMR.

Contrasting Concept: Lysogeny prevalent given low productivity and lysis elevated at high productivity, e.g., Arctic ocean study by Brum et

PtW Claim 1 – In coral reef environments, systems with high microbial abundance have increasing relevance of lysogeny.

However, increasing “temperate-like” genes in the virome could indicate high induction and decreasing relevance of lysogeny (to the extent that weak relationships are present, many of which are not).

Microbes	Provirus-like reads	Method	Bootstrap 95% CI
Log	Linear	Pearson	(-0.37,0.36)
Linear/Log	Linear/Log	Kendall	(-0.13,0.46)
Linear/Log	Linear/Log	Spearman	(-0.15,0.64)
Log	Linear	Robust - Bisquare	(-0.41,0.58)
Log	Linear	Robust - Hampel	(-0.78,0.57)
Log	Linear	Robust - Huber	(-0.95,0.49)

Additional details and methods in:

Weitz, Beckett, Brum, Cael & Dushoff.

Lysis, lysogeny, and virus-microbe ratios, *biorXiv*:

051085

PtW Claim 2 – When increasing relevance of lysogeny is integrated into a dynamic model, then the virus-to-microbe ratio decreases with increasing microbial abundance.

However, there is no lysogeny in the PtW model. Rather, the PtW model is a lytic model where the lysis and viral release increases with increasing cell abundance.

$$\begin{array}{lcl}
 \text{microbial cell change} & & \\
 \underbrace{\frac{dN}{dt}} & = & \underbrace{rN(1 - N/K)}_{\text{microbial growth}} - \underbrace{\phi NP}_{\text{lysis}} - \underbrace{dN}_{\text{microbial mortality}} \\
 \\
 \text{viral particle change} & & \\
 \underbrace{\frac{dV}{dt}} & = & \underbrace{\beta \phi NV \frac{N}{K}}_{\text{viral release}} - \underbrace{mV}_{\text{viral decay}}
 \end{array}$$

Additional details and methods in:

Weitz, Beckett, Brum, Cael & Dushoff.

Lysis, lysogeny, and virus-microbe ratios, *biorXiv*:

051085

PtW Claim 3 - Other models cannot explain this result, hence PTW is the likely mechanism underlying nonlinear VMRs in coral reefs and the global oceans.

However, multiple models – including “Lotka-Volterra” models – can exhibit a declining VMR with increasing microbial cell

Additional details and methods in:

Weitz, Beckett, Brum, Cael & Dushoff.

Lysis, lysogeny, and virus-microbe ratios, *biorXiv*:

051085

My view:

We need better measurements and models of viral and microbial dynamics that can directly test mechanisms based on core principles of virus biology.

In doing so, we may find that not all mechanisms and patterns are universal. Different laws may emerge at different scales and in different oceanic
