

The Tip of the Red Giant Branch (TRGB) : current status and future prospects

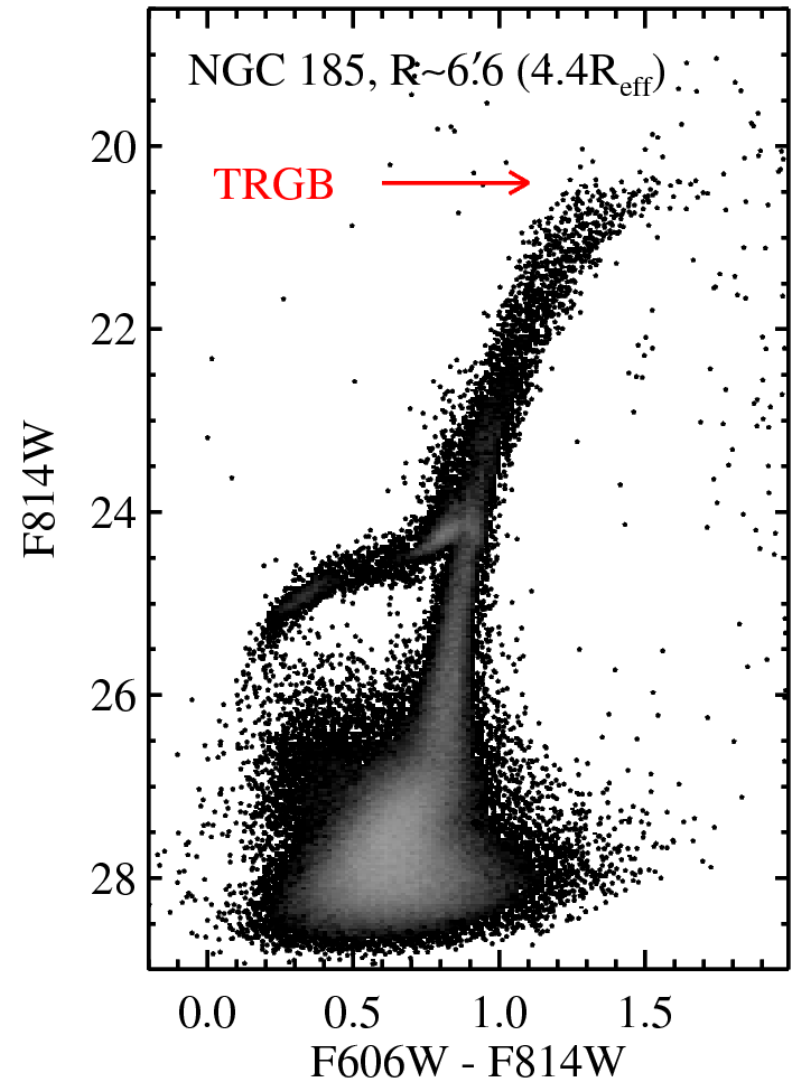

In Sung Jang

Leibniz Institute for Astrophysics Potsdam

The Tip of the Red Giant Branch

TRGB is

- ✓ the brightest part of RGB in the CMD of old stellar systems.
- ✓ seen in any types of galaxies older than a few Gyr.
- ✓ comparable to **Cepheids** in precision (Lee, Freedman, and Madore 1993)
- ✓ now a reliable distance indicator applied to ~300 galaxies (as of Feb 2019, NED).

Contents

1. Comparison of the TRGB with Cepheids
2. Metallicity and Age Dependence of the TRGB
3. Detecting the TRGB with HST and JWST

The background is a light blue gradient. In the upper left, there are white, stylized floral and vine patterns. A large, detailed moon is positioned in the upper center. Several white, four-pointed stars are scattered across the sky. At the bottom, there is a dark silhouette of grass, with more white floral and vine patterns rising from it.

Comparison of the TRGB with Cepheids

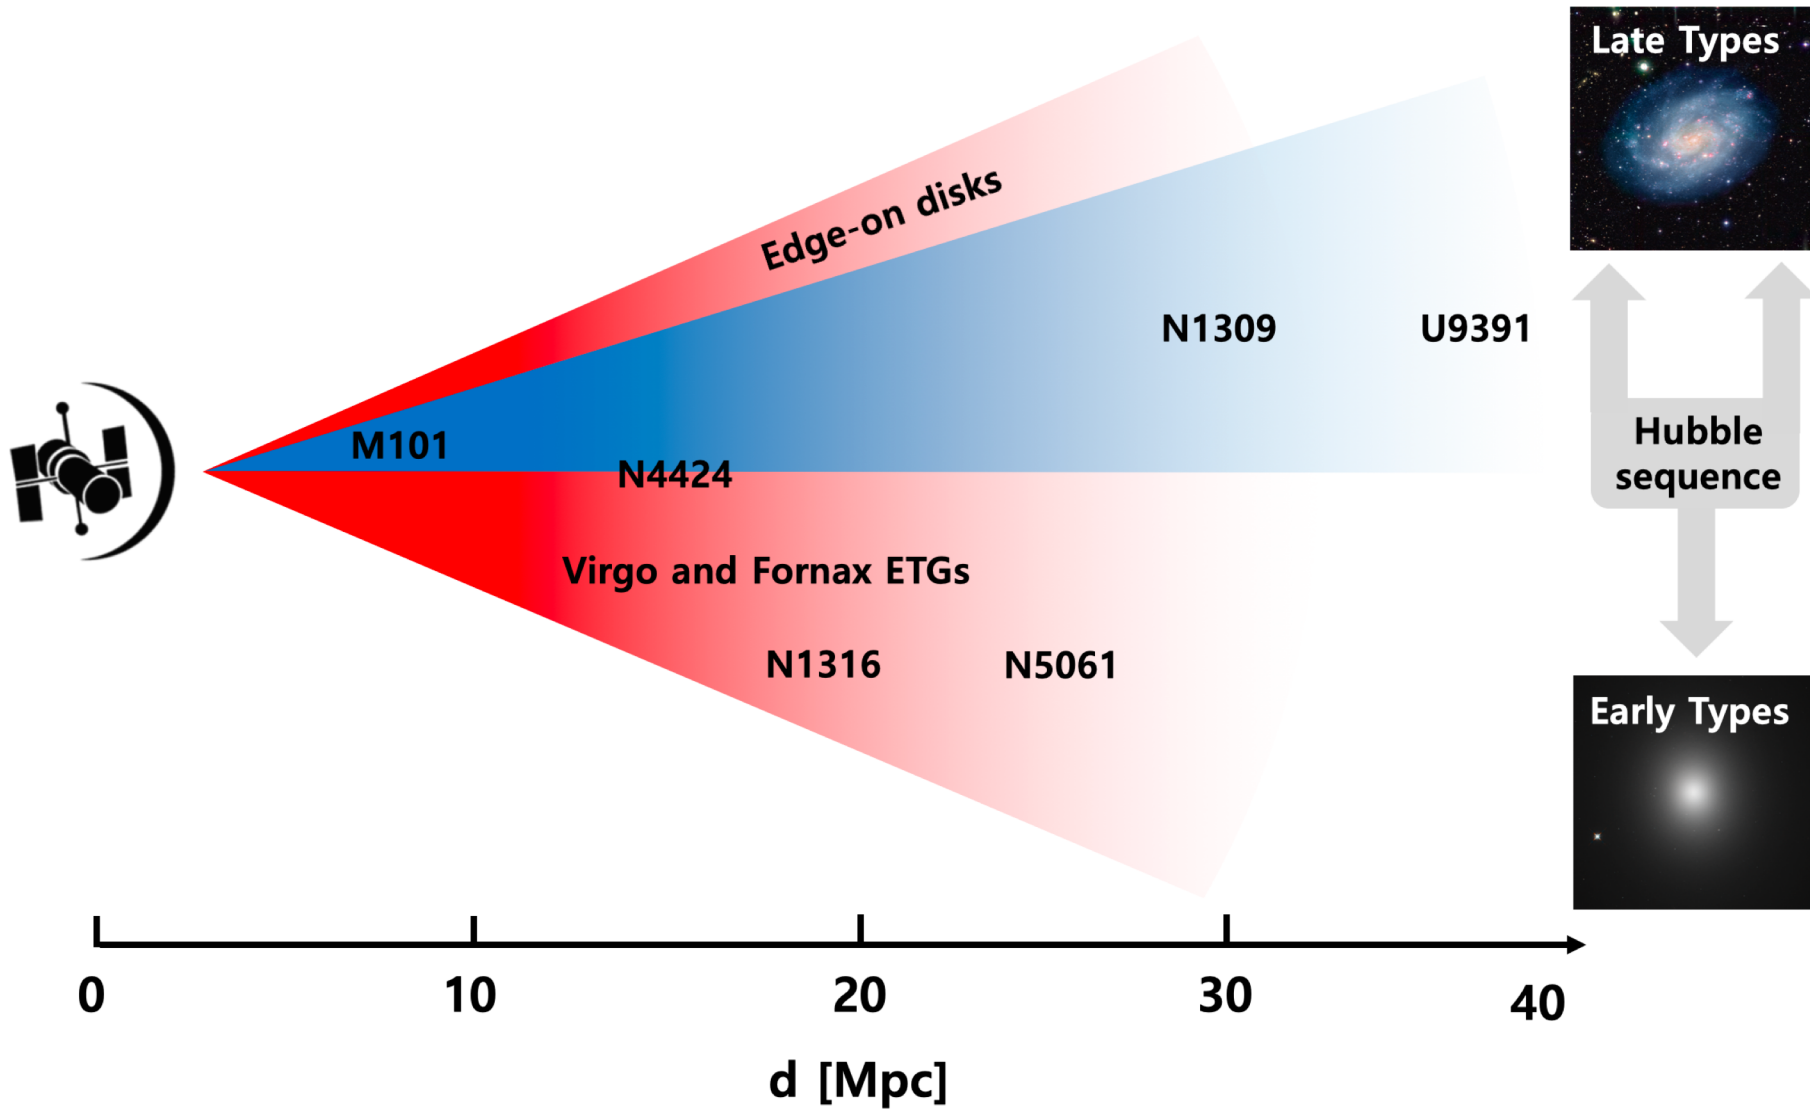

TRGB VS Cepheids

	TRGB	Cepheid
Pros	<ul style="list-style-type: none">• no extinction• in any types of galaxies• non variables• low stellar crowding	<ul style="list-style-type: none">• bright! ($M_{V,\max} \sim -6$)• up to $d \lesssim 40$ Mpc
Cons	<ul style="list-style-type: none">• fainter ($M_I \sim -4.0$)• limited to $d \lesssim 30$ Mpc	<ul style="list-style-type: none">• metallicity effect (controversial)• Interstellar extinction• only in late-type galaxies• Variable stars

Cepheids

TRGB VS Cepheids

TIPSNU and SH0ES

(Jang&Lee+17)

(Riess+16)

✓ JL17 VS R11 (5 SNe)
: $\Delta(m-M)_0 = 0.00 \pm 0.04$ mag

✓ JL17 VS R16 (6 SNe)
: $\Delta(m-M)_0 = 0.02 \pm 0.03$ mag

✓ R11 VS R16 (8 SNe)
: $\Delta(m-M)_0 = 0.02 \pm 0.04$ mag

✓ R11 VS R16 (NGC 4038/39)
: $\Delta(m-M)_0 = 0.45 \pm 0.14$ mag

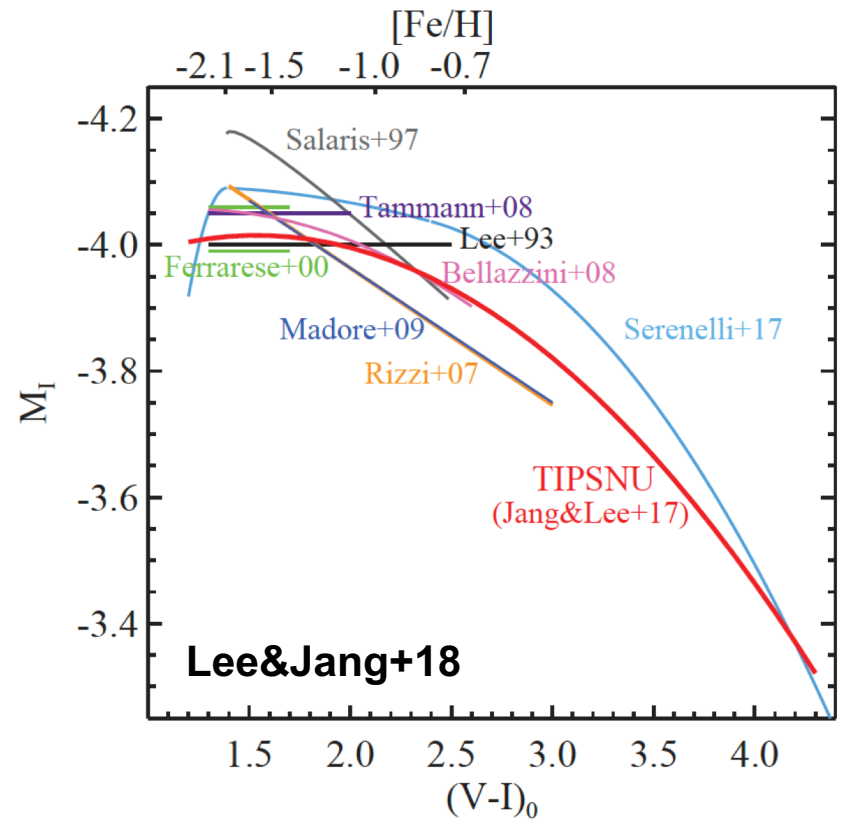

“See Freedman+19 for details”

The background is a light blue gradient. In the upper left, there are white and light blue floral and vine patterns. A large, detailed moon is positioned in the upper center. Several white, four-pointed stars are scattered across the sky. At the bottom, there is a dark silhouette of grass, with more white and light blue floral and vine patterns rising from it.

Metallicity and Age dependence of the TRGB

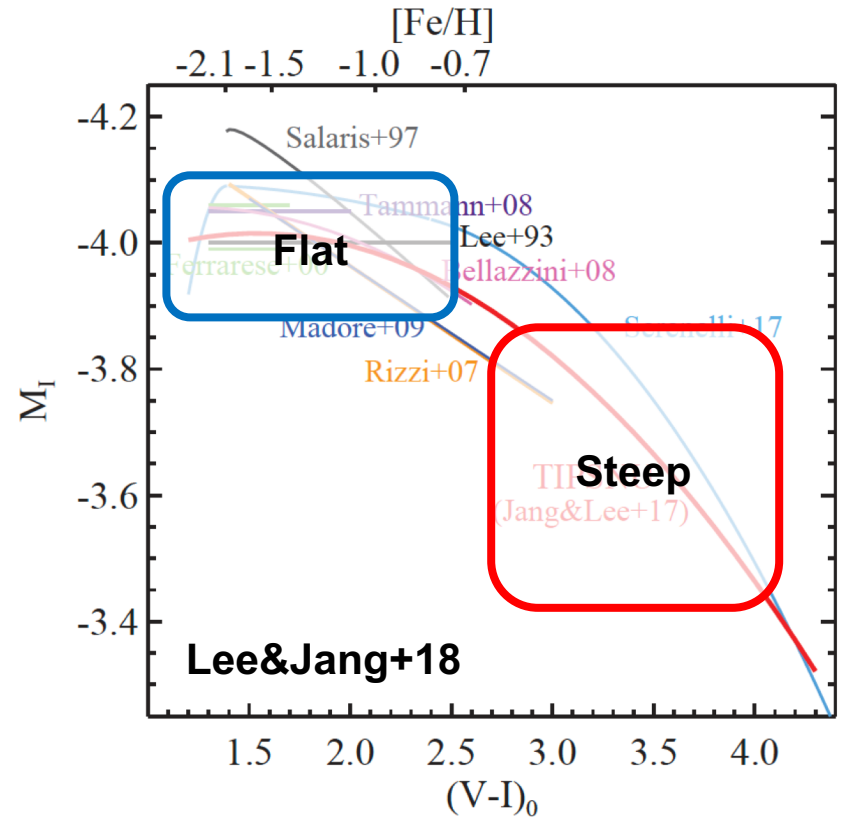

Color (Metallicity) dependence of the TRGB

GHOSTS: A Survey of Nearby Disk Galaxies

“halo stars are **old** and **metal poor!**”

TRGB in the near-infrared

TRGB Morphology with Wavelength

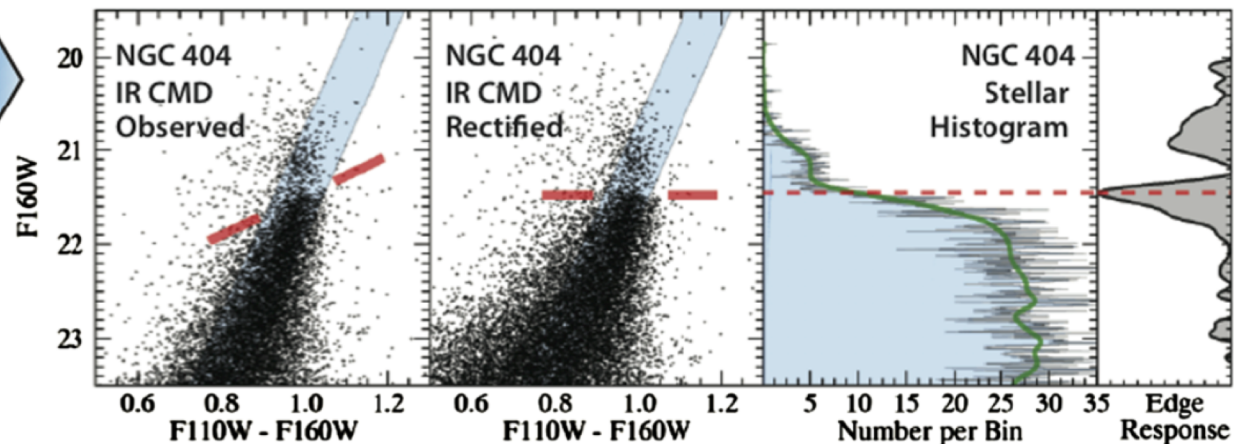

Pros

- brighter TRGB luminosity
- lower interstellar extinction

Cons

- color (metallicity) dependent TRGB luminosity
- color corrected (retified) magnitude required

Age dependence of the TRGB

✓ Observational tests

- using old star clusters (1-12 Gyrs).
- Lack of massive star clusters in the MW

✓ Theoretical predictions

- stellar evolution models

I-band luminosity of the TRGB is stable for old ($\gtrsim 4$ Gyr) stellar systems.

Lee+93, Salaris&Casisi+05, Mcquinn+19

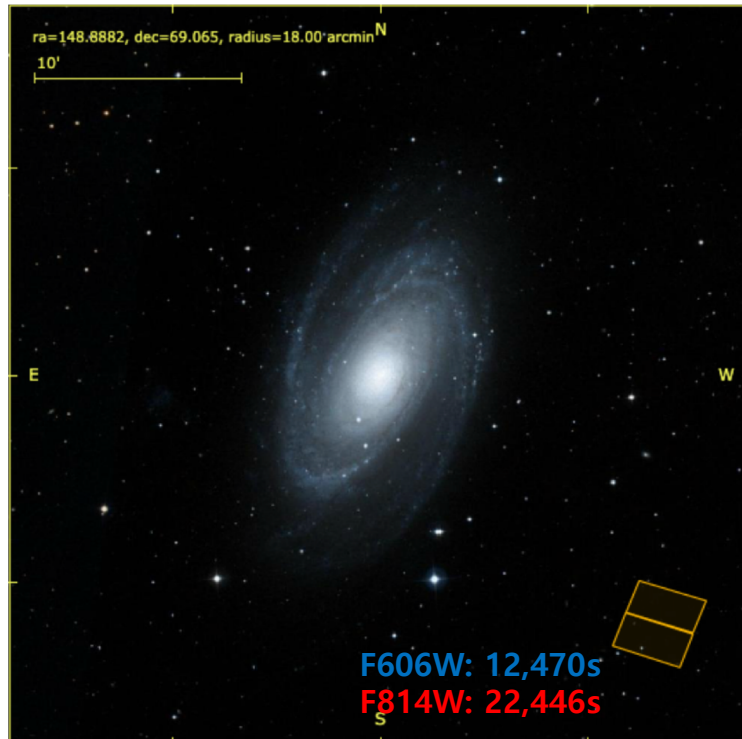

Ages of galaxy outskirts: M31 (Brown+06)

„Each field exhibits an extended SFH with many stars younger than 10 Gyr, but few younger than 4 Gyr.“
Brown+06

Ages of galaxy outskirts: M81 (Durrell+10)

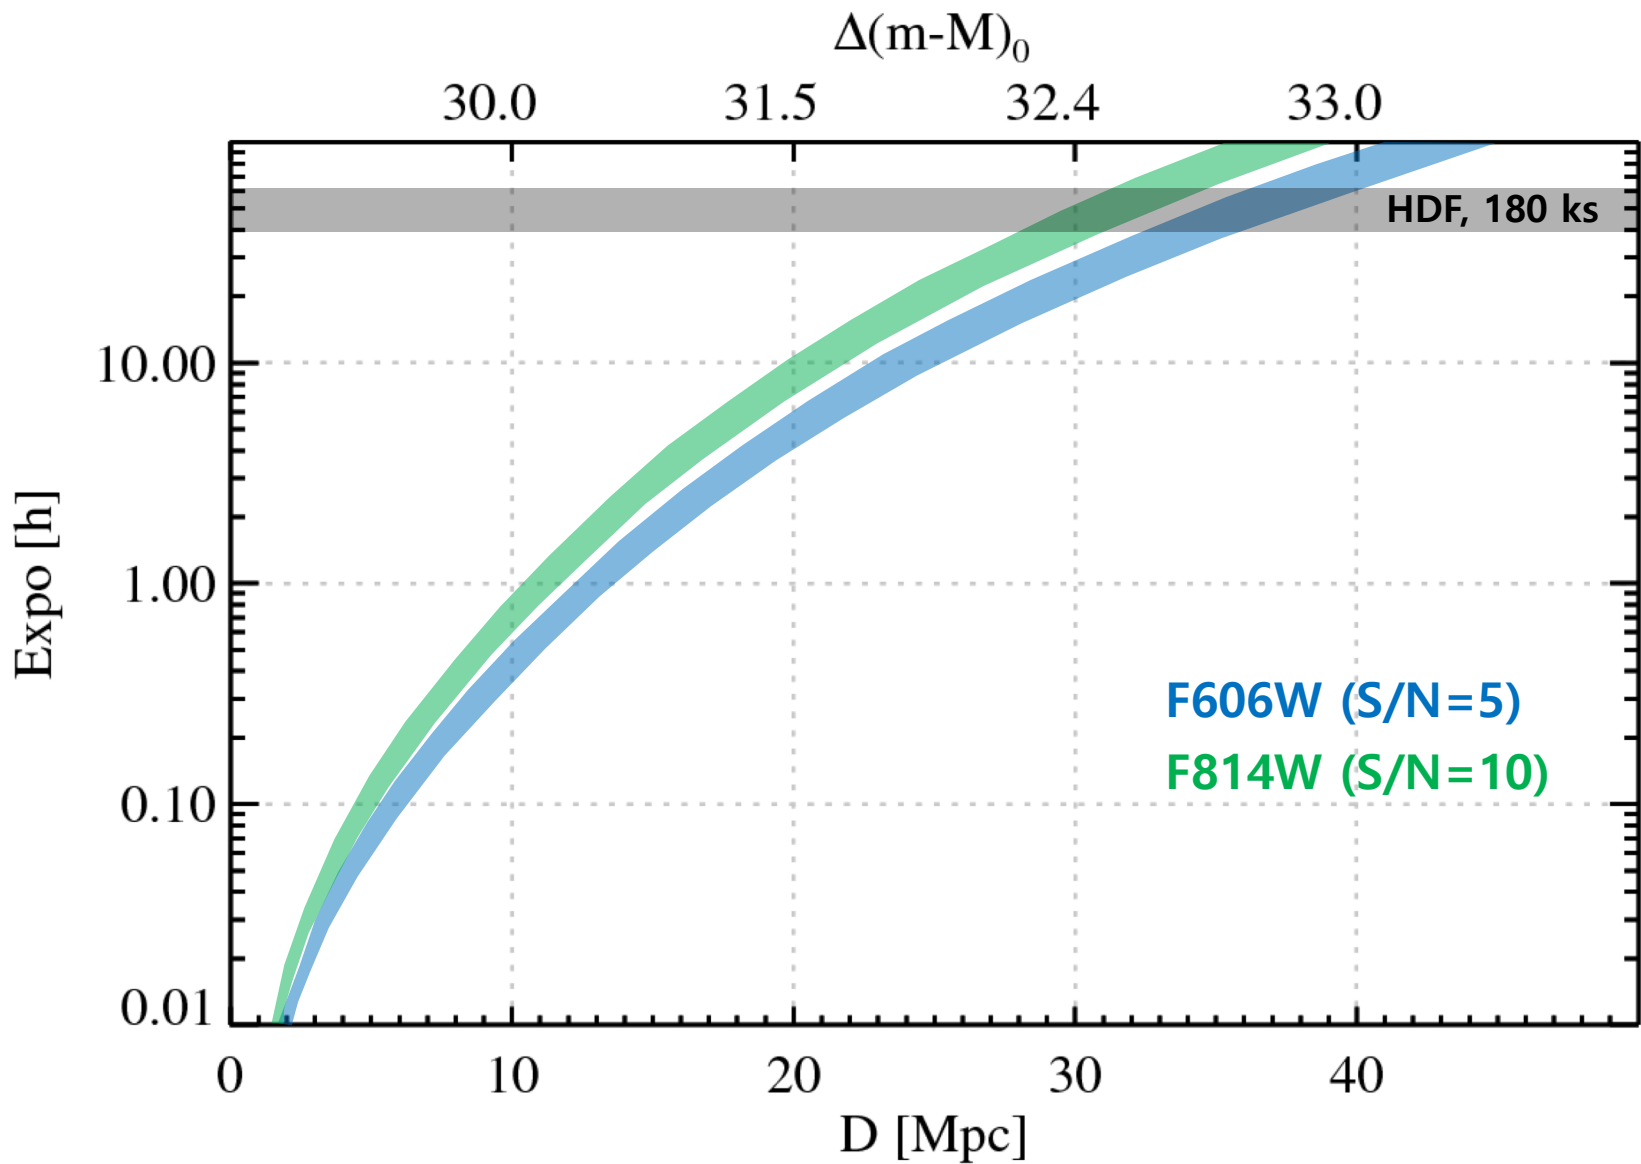

„We derive a mean metallicity of $[M/H] = -1.15 \pm 0.11$ and age of 9 ± 2 Gyr for the dominant population in our field”

The background is a light blue gradient. In the upper left, there are white, stylized floral and vine patterns. A large, detailed moon is positioned in the upper center. Several white, four-pointed stars are scattered across the sky. At the bottom, there is a dark silhouette of grass, with more white floral and vine patterns rising from it.

Detecting the TRGB with HST and JWST

Required exposure times to detect the TRGB

Required exposure times to detect the TRGB

LOOK, AT LEAST THE SLOPE IS LESS THAN ONE.

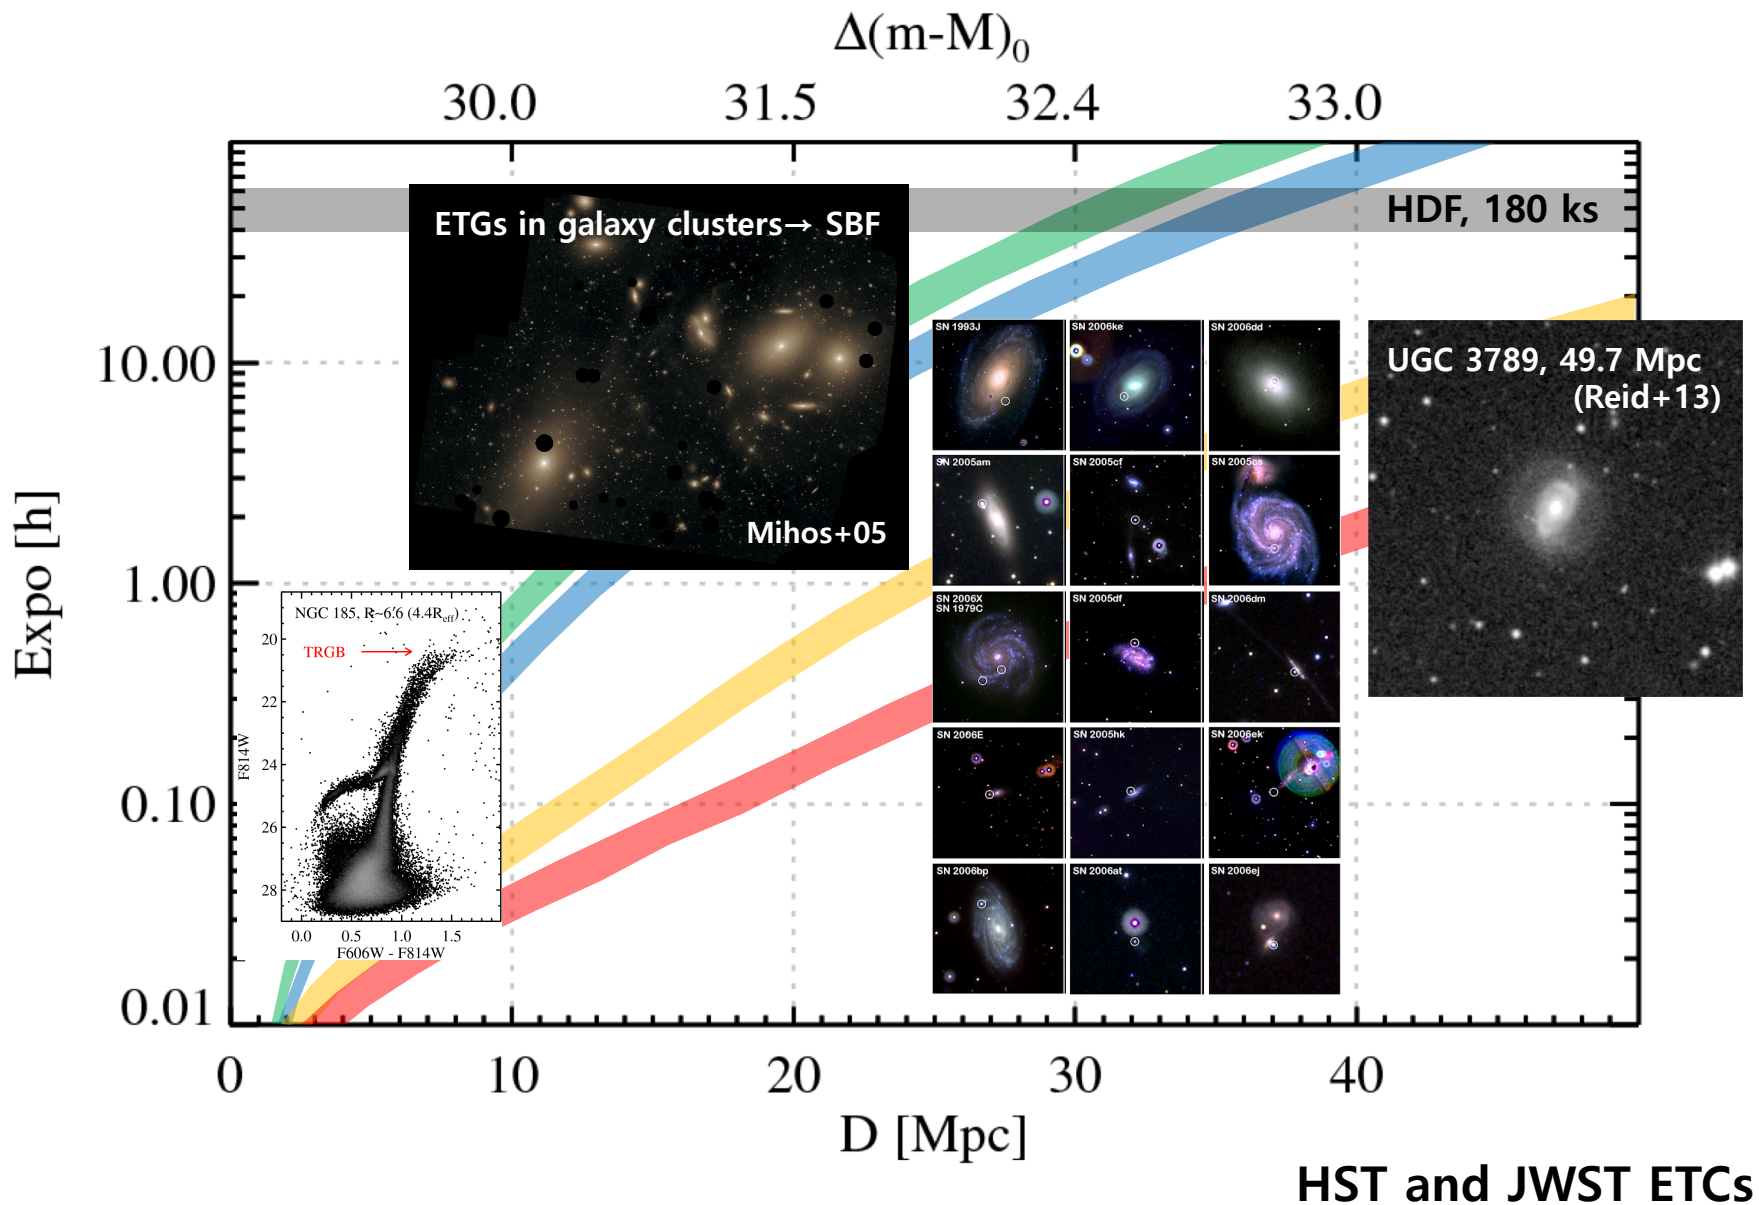

Required exposure times to detect the TRGB

JWST can go ×2 further and will have ×2 higher angular resolution.

Required exposure times to detect the TRGB

**Controlling the background stellar density
: where do we observe?**

Too crowded!

Too sparse!

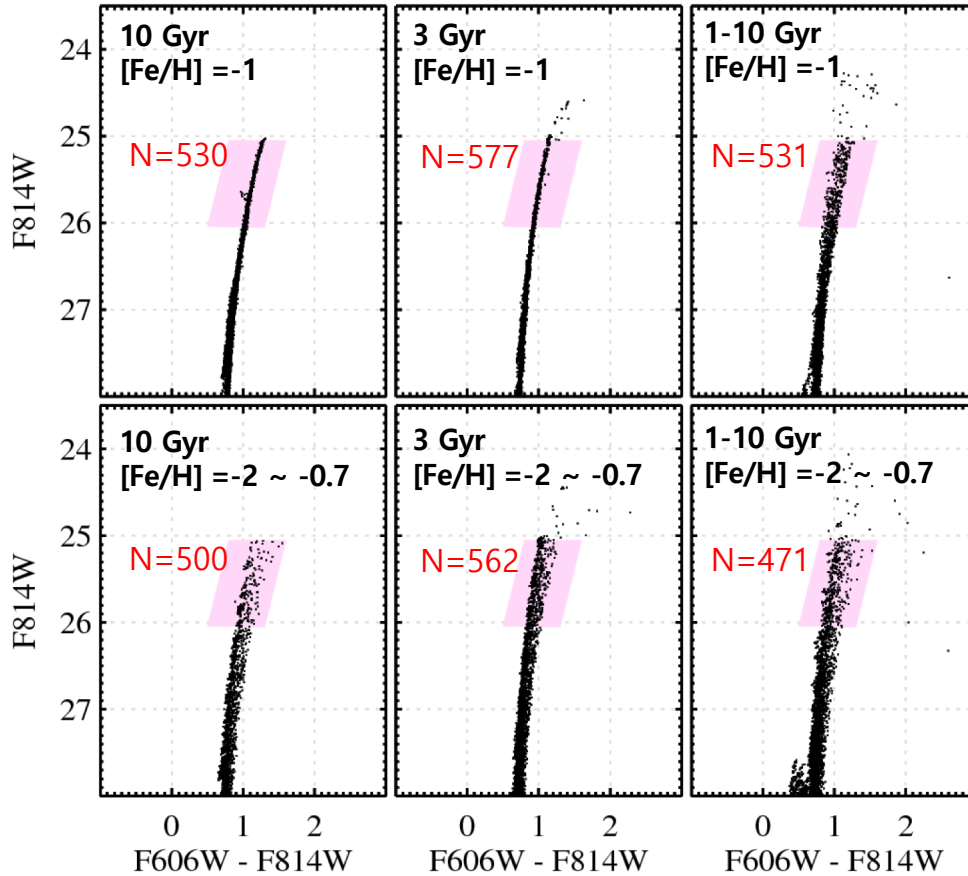

Tests of stellar densities

Mihos+13

Tests of stellar densities

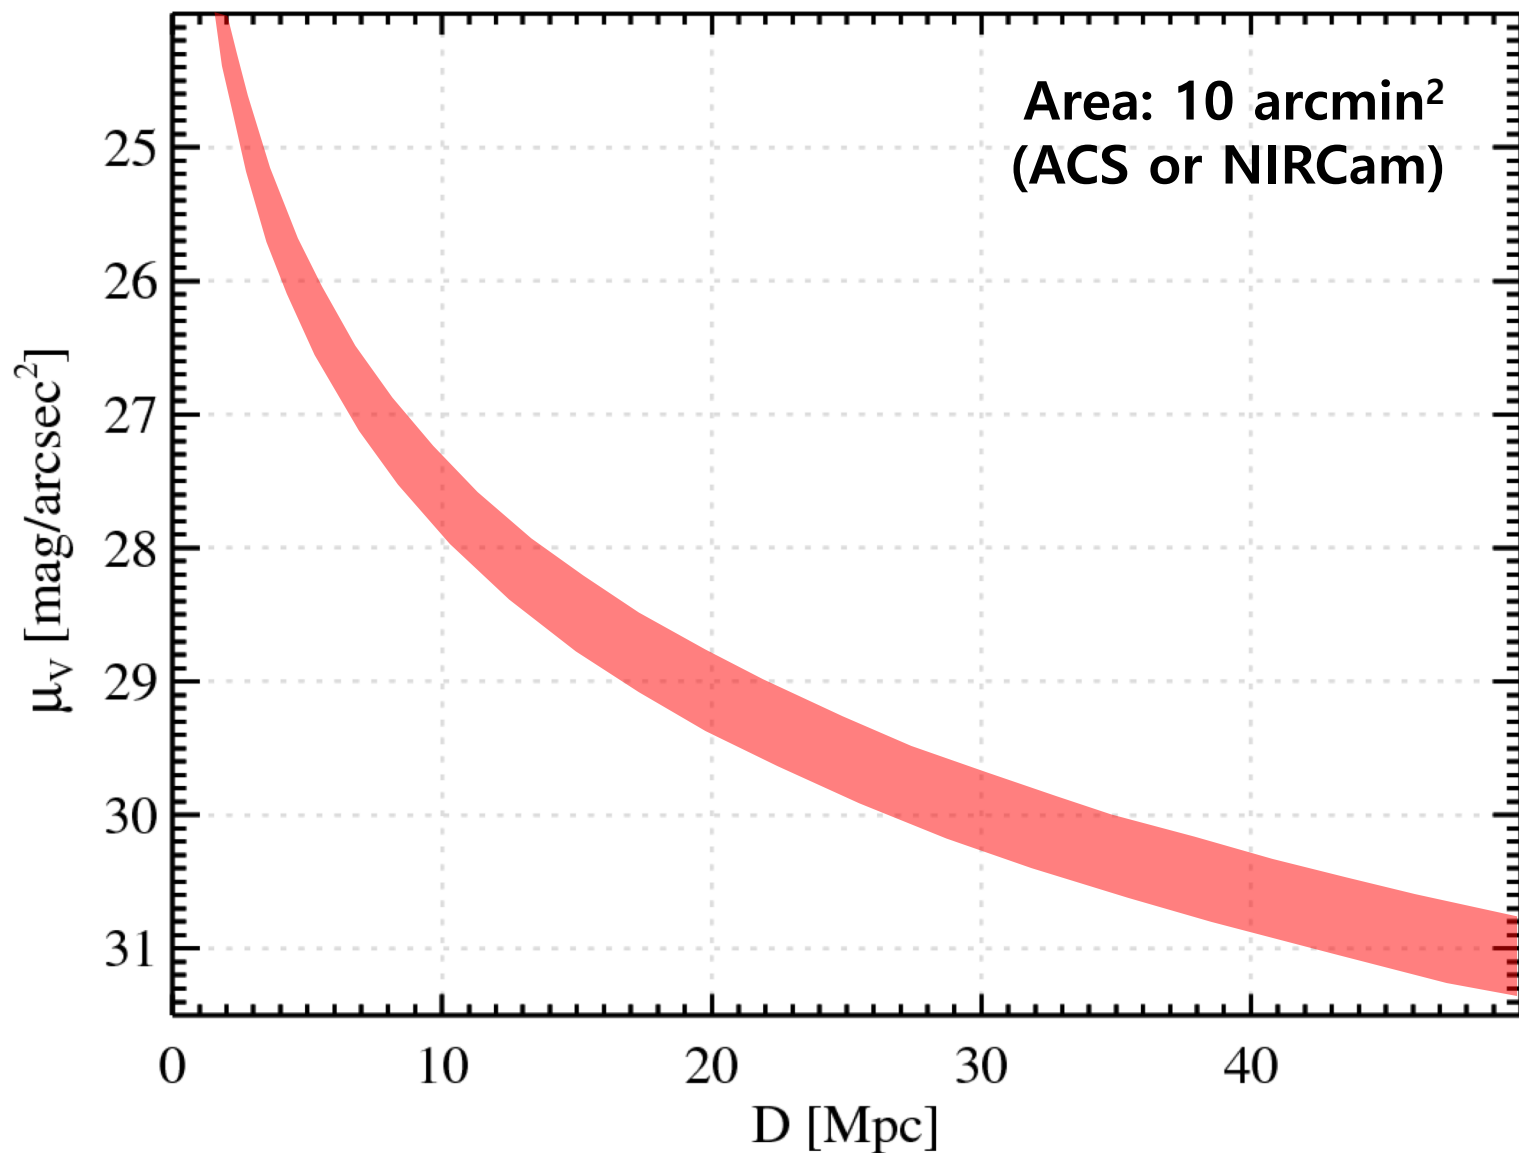

Simulated CMDs, S/N=100

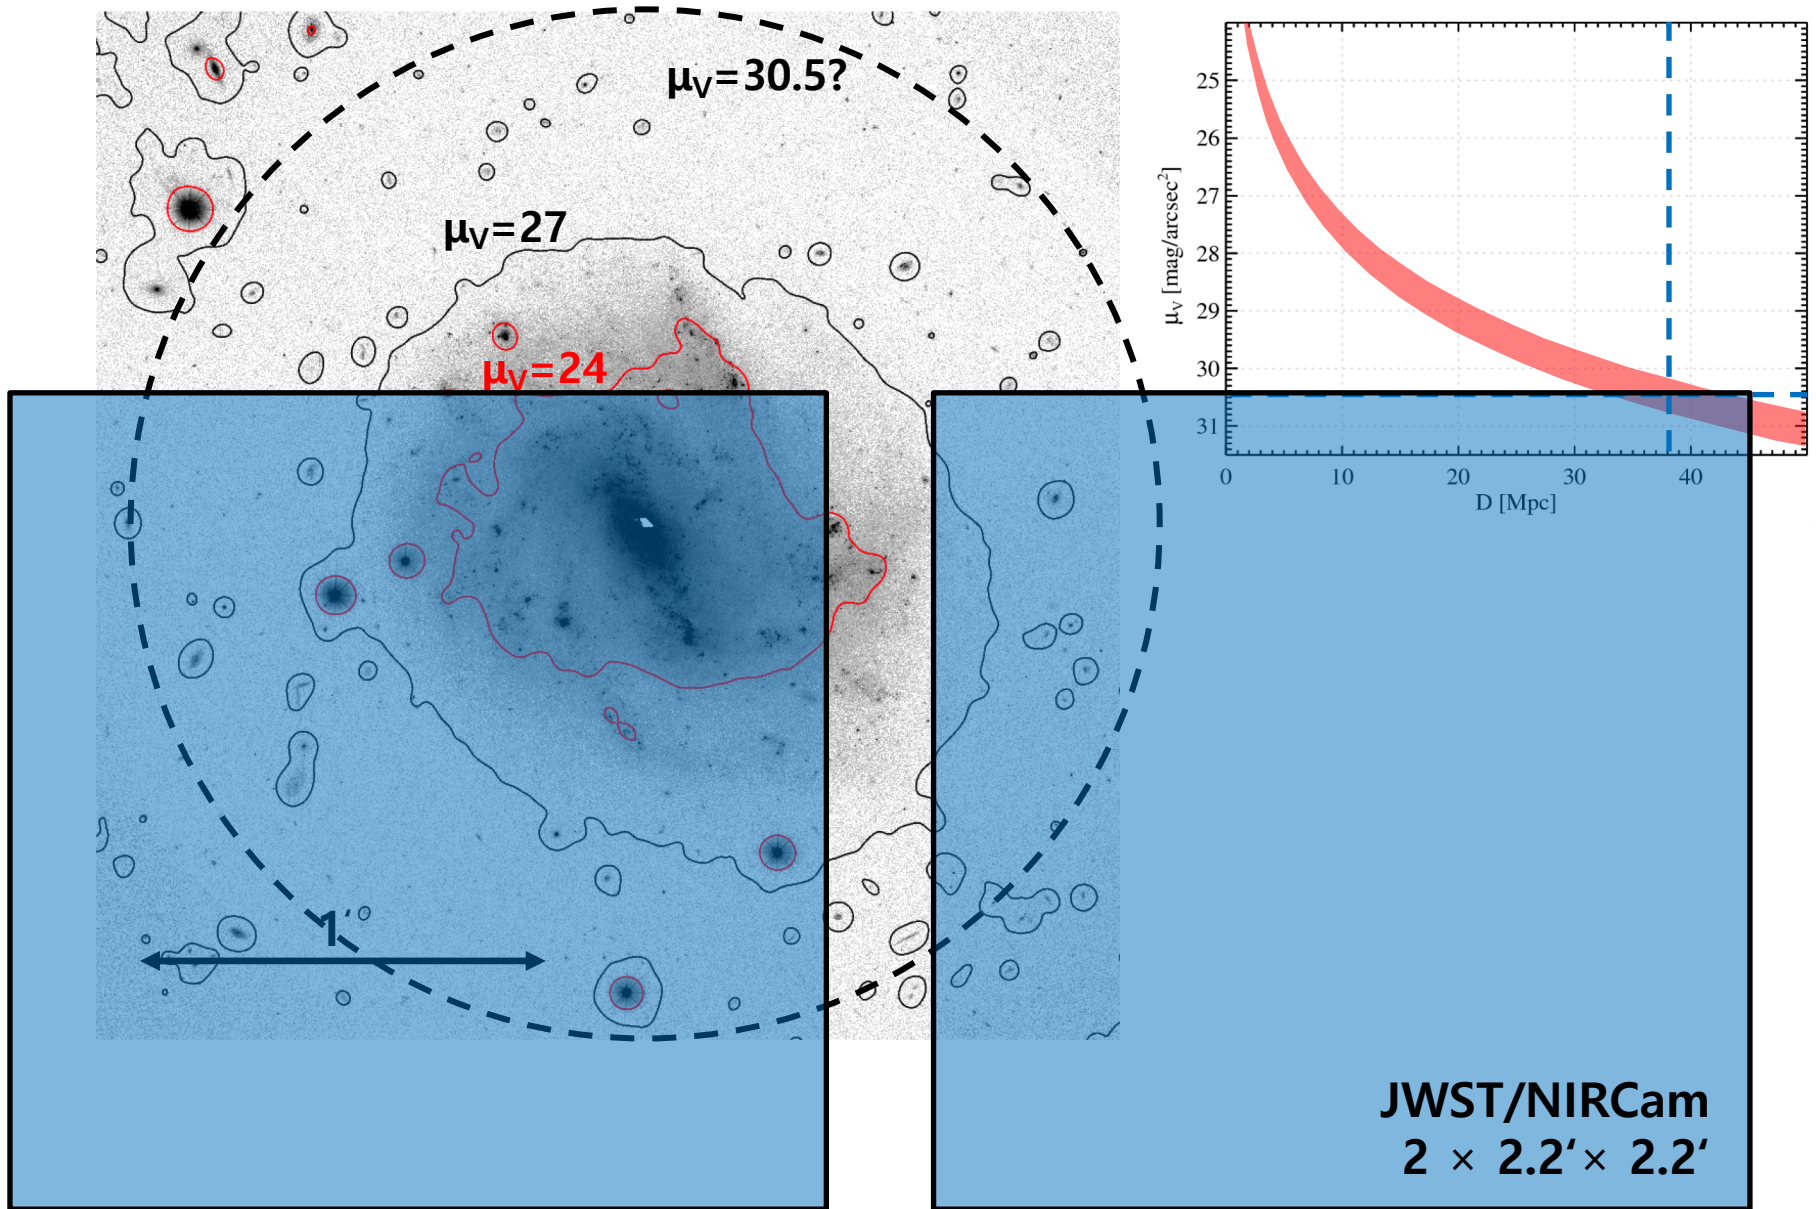

Observed CMD

3000 RGB stars in 1 mag bin below the TRGB

UGC 9391 (SN 2003du), $D = 38.4$ Mpc (Riess+16)

Summary

1. Comparison of the TRGB with Cepheids
 - Two independent distance estimates are in good agreement within uncertainties, but see Freeman+19.
2. Metallicity and Age dependence of the TRGB
 - uncertainties can be minimized down to $\sim 1\%$ in distance.
3. Detecting the TRGB with HST and JWST
 - HST can detect the TRGB out to ~ 30 Mpc.
 - JWST can go out to ~ 50 Mpc, sampling more SNe.

The future of the TRGB method is bright!
