**DNA/Protein World**

# Life as we know it

There are two fundamental requirements for life as we know it, **liquid water and organic polymers, such as nucleic acids and proteins**. Water's unique properties (excellent solvent, exceptionally large liquid temperature range, etc.) make it an ideal medium for chemical reactions to take place. Polymers are needed to carry out the central biological functions of replication and catalysis. Without these vital components, as far as we know, life is impossible.

**“There is no certainty that the existence of water means the existence of life. The other way around is probably true, though.”**  
*David Baltimore, NY Times, March, 2004.*

# Classification of extraterrestrial bodies that could supply exogenous organic compounds based on their size and thermal histories.

---

| Type of object | Size range (m)      | Thermal history  |
|----------------|---------------------|--|
| IDPs           | $<10^{-6}$          | No heating   |
|                | $10^{-6} - 10^{-5}$ | Full depth heating to $<500^{\circ}\text{C}$           |
|                | $10^{-5} - 10^{-3}$ | Full depth heating up to $\sim 1200^{\circ}\text{C}$   |
| Meteorites     | $10^{-3} - 10^2$    | Heating $>600^{\circ}\text{C}$ up to 1 mm depth        |
| Asteroids      | $>10^3$             | Explosive impacts: up to $\sim 10,000^{\circ}\text{C}$ |
| Comets         | $>10^3$             | Airbursts: moderate heating                            |

# Can key organic compounds survive delivery to Earth from space?

Asteroid impacts are much more energetic than a nuclear explosion

IDPs are heated to high T

**A large fraction of compounds such as amino acids would be destroyed during these processes**

# Organic compounds on the early Earth

- Key ingredients such as amino acids are considered necessary for the origin of life.
- Deliver of key organic compounds to the Earth by interplanetary dust, meteorites, comets and asteroids.  
Panspermia in its modern form!!
- ✓ Homegrown synthesis: Miller's spark discharge experiment and others.

**The original Miller/Urey experiment used a reducing gas mixture consisting of methane, ammonia and hydrogen**

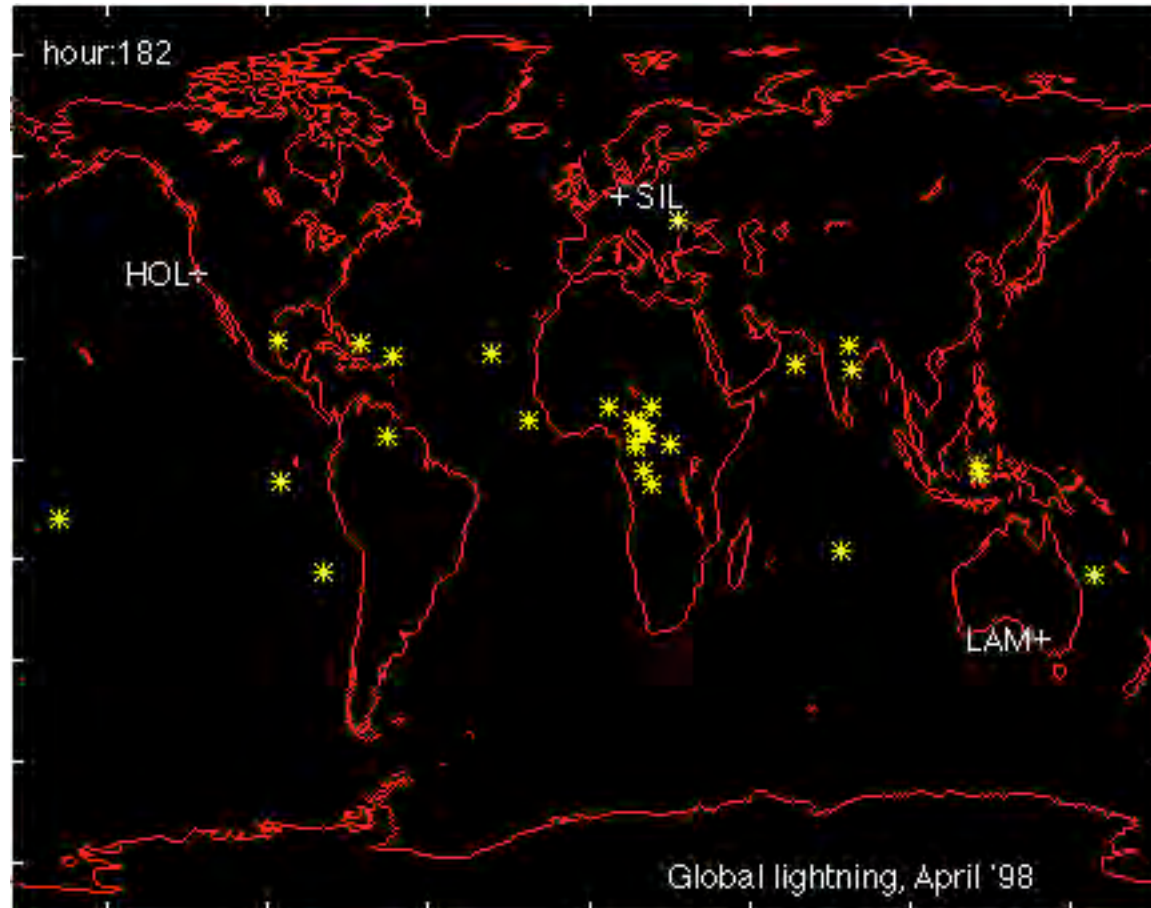

Using a reduced gas mixture a variety of organic compounds were synthesized including amino and hydroxy acids. With non-reducing mixtures, only trace quantities of these compounds were synthesized. Amino and hydroxy acids are synthesized by the reaction sequence below.

# Miller-Urey Synthesis

# Global lightning and coronal discharges are only one possible source of energy

**Other energy sources include ultraviolet radiation, cosmic rays, thermal energy and possibly radioactive decay**

# Atmospheric conditions are key parameters for synthesis

Schlesinger, G. & Miller, S. L., *J. Mol. Evol.* (1983) 19:376-82.

As long as hydrogen is present at sufficient levels, other reduced gases (methane, ammonia, etc.) would be present. Many geoscientists today doubt that the primitive atmosphere was hydrogen rich for more than a few 10s of millions of years.

**Although reducing conditions may not have existed on a global scale, localized high concentrations of reduced gases may have existed around volcanic eruptions especially in hot-spot island-arc systems that may have been common on the early Earth. The localized release of reduced gases by volcanic eruptions on the early Earth would likely have been immediately exposed to intense lightning, which is commonly associated with volcanic eruptions today.**

**Intense volcanic lightning has been reported for nearly all historically observed volcanic eruptions, especially those on ocean islands (see S. R. McNutt, C. M. Davis, Lightning associated with the 1992 eruptions of Crater Peak, Mount Spurr Volcano, Alaska, *J. Vol. Geothermal Res.* 102 (2000), 45-65).**

- **During Pliny The Elder’s AD 79 observations of the Vesuvius eruption, in which he perished, intense volcanic lightning was reported.**
- **Captain MacKenzie of the *Zeeland* passed within 5 miles of the 1883 Krakatoa explosion and reported that a “black cloud rose swiftly above the mountain, with lightning flashes deep within the clouds, and a continuous crackling sound”.**

# Miller's other apparatus tested in the 1950s experiments mimicked lightning associated with volcanic eruptions

## Yields for Miller's experiments with the original and volcanic apparatus

**S. L. Miller, Production of some organic compounds under possible primitive Earth conditions, *JACS* 77, 2351-2361 (1955).**

# Atmospheric conditions are key parameters for synthesis

Schlesinger, G. & Miller, S. L., *J. Mol. Evol.* (1983) 19:376-82.

**Note that with both the CO and CO<sub>2</sub> mixtures that even some amino acids are produced in the absence of hydrogen.**

# What are the actual yields with $\text{CO}_2/\text{N}_2$ mixtures?

| <b>Experiment</b>      | <b>Final pH</b> | <b>NH<sub>3</sub></b> | <b>HCN</b>         | <b>NO<sup>2-</sup></b> | <b>NO<sup>3-</sup></b> | <b>HCHO</b>         |

**It is important to note that in the presence of nitrate and nitrite, when a mixture is acid hydrolyzed the amino acids are destroyed. The addition of ascorbic acid prior to hydrolysis prevents this from taking place.**

**Figure 1.** Typical HPLC chromatograms of the OPA-NAC derivitized amino acids detected from the spark discharge reactions. Chromatograms labeled with roman numerals: I.) Amino acid standard, II.) CO<sub>2</sub>/N<sub>2</sub> not sparked, III.) CO<sub>2</sub>/N<sub>2</sub> + CaCO<sub>3</sub>, sparked, hydrolyzed – ascorbate. IV.) CO<sub>2</sub>/N<sub>2</sub>, sparked, hydrolyzed - ascorbate **V.) CO<sub>2</sub>/N<sub>2</sub>, s parked + CaCO<sub>3</sub>, h ydrolyzed + ascorbate.** Amino acids: 1.) DL aspartic Acid 2.) DL glutamic Acid 3.) DL serine 4.) glycine 5.) β-Alanine 6.) DL alanine 7.) α-amino Isobutyric acid 8.) DL norleucine (internal standard). The D and L enantiomers of glutamic acid and se rine are not separated under these chromatographic conditions.

**Table 1.** Yields of amino acids and other small molecules from neutral atmosphere electric discharge reactions sparked 48 hours at room temperature. Yields are calculated based on input N<sub>2</sub> or CO<sub>2</sub> (for HCHO) from 100 mm CO<sub>2</sub>, 100 mm N<sub>2</sub> and 100 mL H<sub>2</sub>O with or without 2 mmoles CaCO<sub>3</sub> in a 3.1 l flask at 23° C. Yields of T HAA (Total Hydrolyzable Amino Acids) are shown after hydrolysis in the absence (-) or presence (+) of ascorbate. ND = not determined.

# Conclusions

- The low yields found previously were the result of oxidation of the organic compounds during hydrolytic workup by nitrite and nitrate produced in the reactions.
- Addition of oxidation inhibitors prior to hydrolysis results in the recovery of several hundred times more amino acids than reported previously.
- Organic synthesis from neutral atmospheres may thus have depended as much on oceanic conditions as on the characteristics of the primitive atmosphere itself.
- **These findings indicate the importance of prebiotic syntheses on the primitive Earth endowed with a CO<sub>2</sub>/N<sub>2</sub>-rich atmosphere, even in the presence of trace amounts of oxygen.**

Where else could this happen in our solar system?

Mars, satellites of the gas giant planets?

Origin of life and evolution
