

Michael Jura (UCLA)

Extrasolar Cosmochemistry

Is Earth “normal”?

UCLA Ph.D.’s -- Siyi Xu; Beth Klein

E. Young + B. Zuckerman + D. Koester

Talk Outline

- ▶ 1. White dwarfs and their pollutions
- ▶ 2. Zero order results: basic compositions
- ▶ 3. First order results: differentiation, ^{26}Al widespread, solar system “ordinary”

Enabled by:

- ▶ Spitzer Space Telescope
- ▶ Keck/HIRES – University of California
- ▶ HST/COS
- ▶ NSF + NASA

Types of Solid Planets?

- ▶ Earth-like
- ▶ Ice-rich
- ▶ Iron-rich
- ▶ Carbon-rich
- ▶ Refractory-rich
- ▶ ???

Extrasolar Planetary Physics

- ▶ Do they differentiate into cores, mantles and crusts?
- ▶ Are mutual collisions important in their formation and evolution?
- ▶ What important physical processes occur in the protoplanetary disk? (like “snow lines”)

Earth: Largely 4 elements – O, Mg, Si, Fe; we live on a “dry” carbon desert

- ▶ $[C]/[Fe] \sim 0.015$ [by mass] in bulk Earth
- ▶ $[C]/[Fe] \sim 1.8$ [by mass] in the Sun
- ▶ Less than 1% water
- ▶ Elements with condensation $T < 1100$ K are deficient
- ▶ Differentiated: core/mantle/crust

Main Story

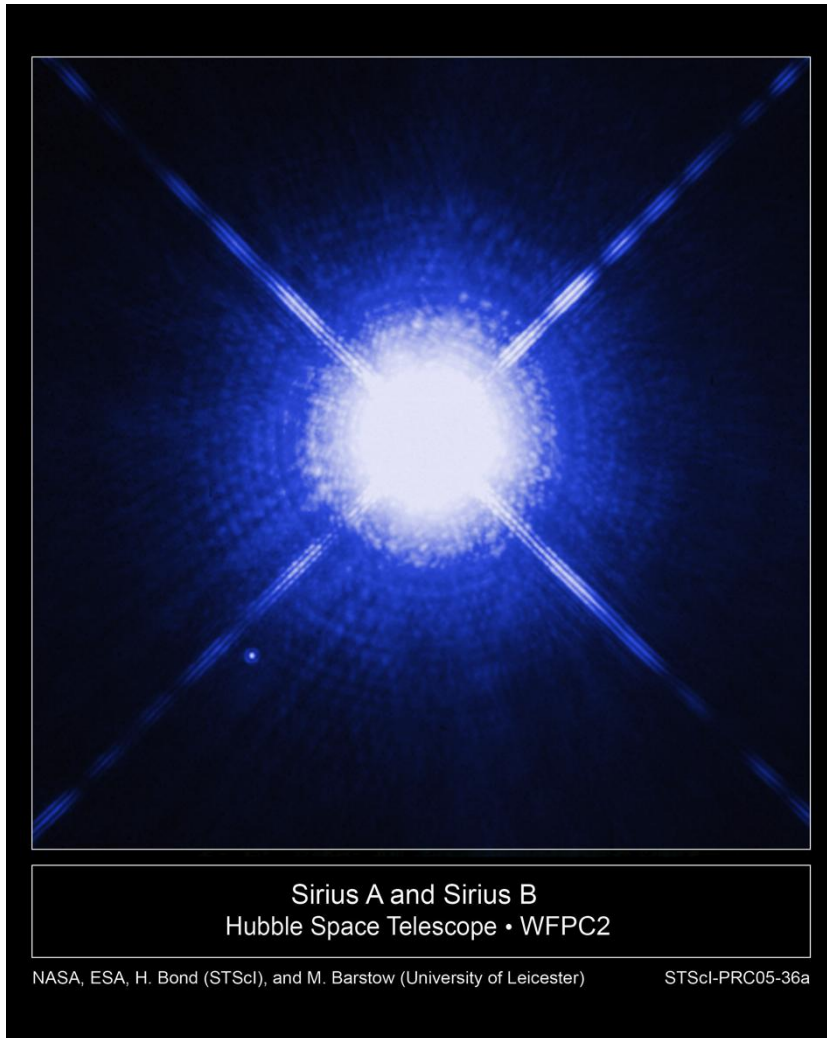

White dwarfs
“smash” asteroids
that stray within the
tidal radius – forming
an orbiting ring of
material (sometimes
dusty)

- ▶ Material then accretes from disk into stellar atmosphere

White Dwarfs

- ▶ Radius ~ Earth
- ▶ Mass ~ 0.6 mass (Sun)
[substantial mass-loss]
- ▶ Very high gravity
- ▶ Cooling embers,
characterized by
atmospheric
temperature
- ▶ Fate of Sun
- ▶ Common: ~10% of
nearby stars (but very
faint and hard to find)

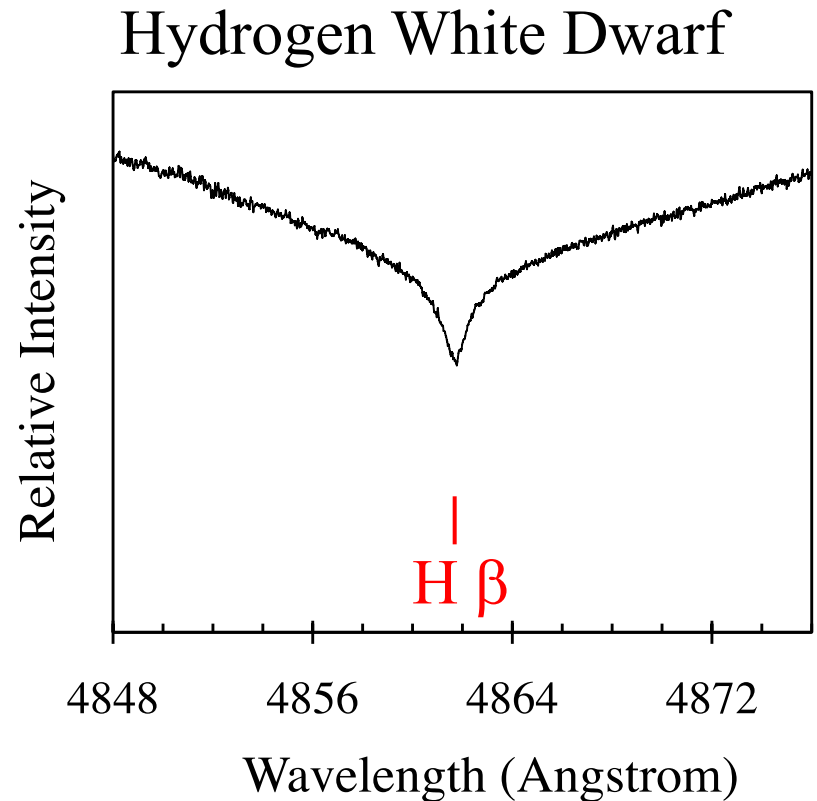

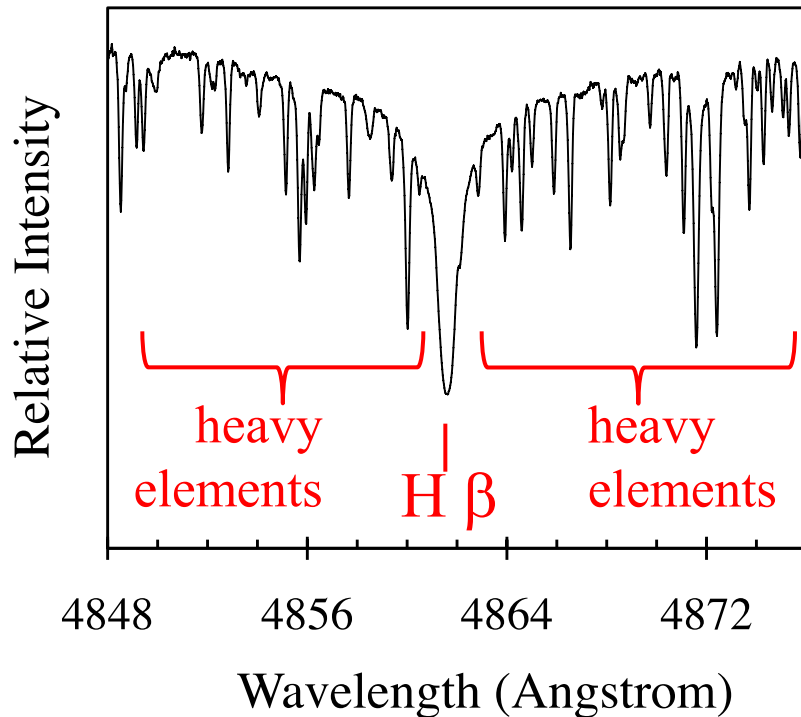

Expectations for White Dwarfs with atmospheric temperature, $T_{\text{eff}} < 20,000$ K

- ▶ High gravity: settling time of heavy elements < 1 Myr; always much less than cooling age of > 0.1 Gyr
 - ▶ Usually: atmosphere pure H or pure He
 - ▶ NO HEAVY ELEMENTS
-

Pure H and/or He Atmospheres

“ It is well known that white-dwarf spectra have only a remote resemblance to spectra of ordinary stars. ”
- Kuiper, 1941

Examples of Externally-Polluted White Dwarfs

- ▶ Cooling Ages ~ 4 Gyr
- ▶ Ca settling time ~ 1 Myr
- ▶ $[\text{Ca}]/[\text{He}] \ll \text{Solar Ratio}$

Famous Comparison Object

- ▶ White dwarfs are smaller than Saturn
 - ▶ White dwarf rings are larger than Saturn's; dust rather than ice
 - ▶ ~4% of warm white dwarfs have dust rings; ~25% are externally-polluted
-

Disk model and data for GD 133

- ▶ $T(\text{inner}) = 800\text{-}1200\text{ K}$ (silicate sublimation)
- ▶ $T(\text{outer}) = 300\text{-}600\text{ K}$ (tidal radius)
- ▶ Tilt of disk uncertain
- ▶ Note: linear scale
- ▶ Factor of 400 less flux at 24 microns than expected for accretion of interstellar grains – disfavored model

Minimum Accreted Masses similar to that of asteroids

- ▶ GD 362 -- 3% of Ceres
- ▶ GD 40 -- 4% of Ceres
- ▶ WD J0738+1835 – 70% of Ceres
- ▶ We are studying building blocks of extrasolar rocky planets

Keck Spectra of GD 40

HST Spectra of GD 40 and G241-6

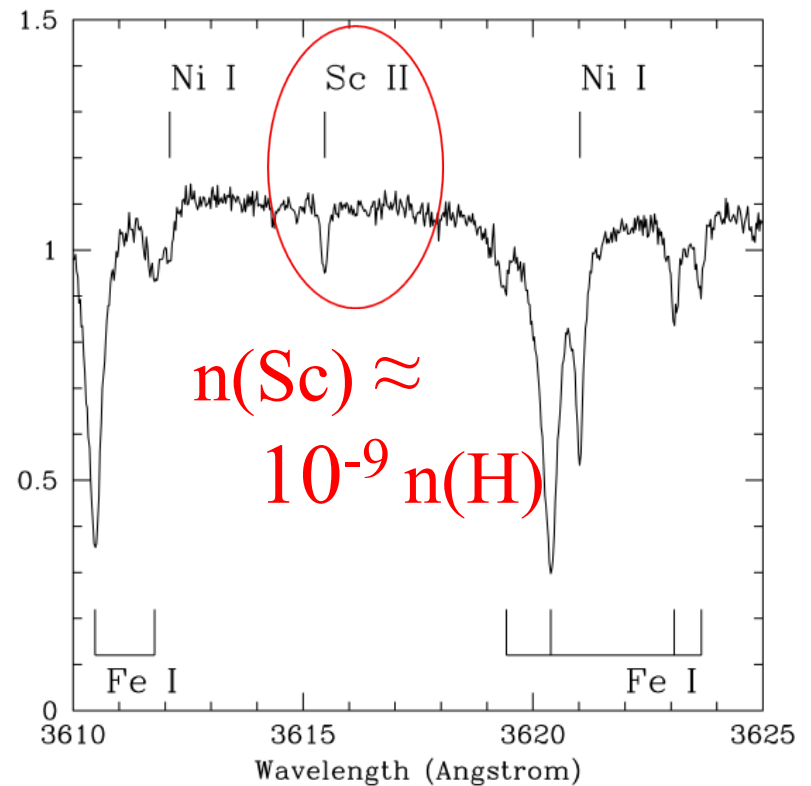

High resolution spectroscopy: exquisitely sensitive to even trace amounts of material.

Inventory of Detected Heavy Elements

- ▶ 19 heavy elements positively detected in some star:
- ▶ C, O, Na, Mg, Al, Si, P, S, Ca, Sc, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Sr
- ▶ Most Richly Polluted White Dwarfs (All have dust disks):
 - ▶ GD 362 – 16 elements
 - ▶ WD J0738+1835 – 14 elements
 - ▶ GD 40 – 12 elements
 - ▶ WD 1929+012 – 12 elements
- ▶ Most elements only seen in a few stars

Carbon Deficiencies

- ▶ Logarithmic Scale: carbon deficient by orders of magnitude
- ▶ Carbon mass fractions similar to Solar System rocks – not Interstellar
- ▶ Almost certainly occurs during asteroid formation within disk

Why is carbon so deficient?

- ▶ Carbon in solid interstellar grains (depleted from gas phase, 2200 Å feature in the ultraviolet) + PAHs
- ▶ Once vaporized, it can form volatile gases like CO but how does this happen?
- ▶ “... the accretion disk at the radius of the asteroid belt probably was never hot enough to vaporize all solids.”
--McSween + Huss (2010) in Cosmochemistry

Evidence for Snow Lines?

- ▶ Internal water survives AGB evolution – thermal conduction takes too long to heat up interior
- ▶ Ice and/or hydrated minerals?

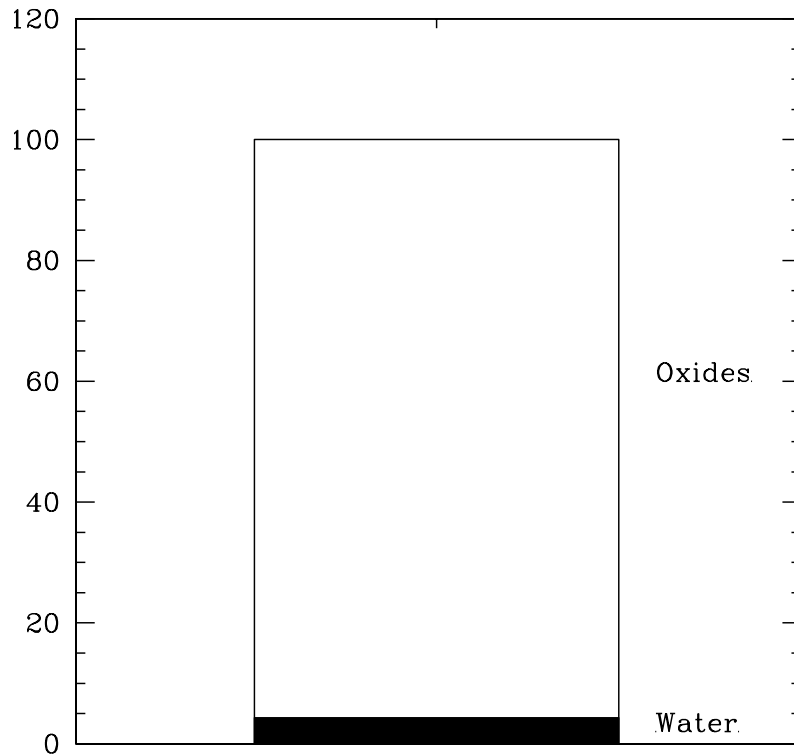

Little Water in Planetesimal Accreted by WD J0738+1835

- ▶ $T = 13,950 \text{ K}$
- ▶ $0.84 M(\text{Sun})$ – White Dwarf
- ▶ $4.5 M(\text{Sun})$ – Main Sequence
- ▶ $m(g) = 17.6 \text{ mag}$ (SDSS)
- ▶ $< 1\%$ water from small amount of H compared to heavy elements in this He-rich atmosphere

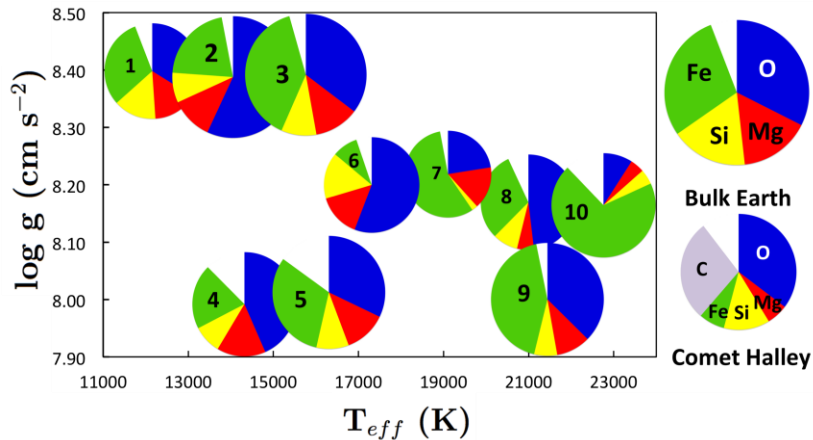

Oxygen Budget: Ensemble of Local He-Atmosphere White Dwarfs

- ▶ Volume-limited sample within 80 pc (57 stars)
- ▶ Little H, most O must be assigned to oxides of Si, Mg, Ca and Fe

Results -- Earth-like objects (0th order)

- ▶ Dominated by 4 elements: O, Mg, Si, Fe
- ▶ Carbon – typically very deficient
- ▶ Typically low in water
- ▶ Evidence for differentiation; both high Fe and low Fe objects

Minor Constituents: Mn/Fe vs. Cr/Fe

- ▶ Mn more volatile, wider spread in Mn/Fe than Cr/Fe; also seen among chondrites

Minor Constituents: Ni/Fe vs. Cr/Fe

- ▶ Pattern “familiar”
- ▶ Data/analysis consistent among different groups

Patterns in the Ensemble: Mg, Si, Fe

- ▶ Greater variation of Fe than Mg – core formation?
- ▶ No systems are purely “crustal”
- ▶ Not just chondritic
- ▶ Evidence for Differentiation

Fe/Al vs. Si/Al

- ▶ Large range in Fe/Al – NOT stellar
- ▶ Differentiated objects

Iron Planets?

- ▶ KOI 1843.03 period of 4.2 hours
- ▶ Mean density $\sim 7 \text{ g cm}^{-3}$
- ▶ Probably largely composed of Fe

26 Aluminun is Widespread

- ▶ Explains widespread differentiation
- ▶ Explains gamma ray background if confined to molecular clouds
- ▶ Solar system was **NOT** unusual

Summary

- ▶ At 0-order, extrasolar minor planets resemble bulk Earth (mostly O, Mg, Si, Fe, little C or water)
- ▶ No known C, Al/Ca/O, or kryptonite planets
- ▶ Differentiation: cores + crusts
- ▶ Solar system normal, ^{26}Al widespread
