increases sharply with
metallicity of host star

Hydrodynamical models of planetesimal formation exhibit similar sharp dependence on metallicity

Planet formation

Planetesimal hypothesis of Safronov 1969:

Planets form in protoplanetary discs from dust grains that collide and stick together

① Dust to planetesimals

$\mu\text{m} \rightarrow \text{cm}$: contact forces during collision lead to sticking
 $\text{cm} \rightarrow \text{km}$: ???

② Planetesimals to protoplanets

$\text{km} \rightarrow 1,000 \text{ km}$: gravity

③ Protoplanets to planets

Gas giants: $10 M_{\oplus}$ core accretes gas ($< 10^6$ – 10^7 years)
Terrestrial planets: protoplanets collide (10^7 – 10^8 years)

Planet
formation

Planetesimals

Streaming
instability

Metallicity

Self-gravity

Conclusions

- Kilometer-sized objects massive enough to attract each other by gravity (two-body encounters)
- Assembled from colliding dust grains
- *Building blocks of planets*
- Problems:
 - Pebbles, rocks and boulders:
 - drift rapidly through the disc
 - have terrible sticking properties
 - Protoplanetary discs are turbulent

William K. Hartmann

Conclusions

- Kilometer-sized objects massive enough to attract each other by gravity (two-body encounters)
- Assembled from colliding dust grains
- *Building blocks of planets*
- Problems:
 - Pebbles, rocks and boulders:
 - drift rapidly through the disc
 - have terrible sticking properties
 - Protoplanetary discs are turbulent

William K. Hartmann

Planetesimal formation must

- 1 proceed quickly
- 2 not rely on sticking between large solids
- 3 operate in a turbulent environment

Streaming instability

Youdin & Goodman 2005:

(see also Goodman & Pindor 2000)

- **Gas** orbits slightly slower than Keplerian
- **Particles** lose angular momentum due to headwind
- **Particle clumps** locally reduce headwind and are fed by isolated particles

Clumping

Linear and non-linear evolution of radial drift flow of meter-sized boulders:

Strong clumping in non-linear state of the streaming instability

(*Youdin & Johansen 2007; Johansen & Youdin 2007; also Bai & Stone in preparation*)

Metallicity

Self-gravity

Conclusions

Clumping in 3-D

3-D evolution of the streaming instability:

- Particle clumps have up to **100 times** the gas density
- Clumps dense enough to be gravitationally unstable
- But still too simplified:
 - ⇒ no vertical gravity and no self-gravity
 - ⇒ single-sized particles

This talk

⇒ 3-D hydrodynamical simulations of particle sedimentation, including multiple sizes, clumping and self-gravity

Planet
formation

Planetesimals

Streaming
instability

Metallicity

Self-gravity

Conclusions

Why is metallicity important?

- **Gas** orbits slightly slower than Keplerian
- **Particles** lose angular momentum due to headwind
- **Particle clumps** locally reduce headwind and are fed by isolated particles

- *Clumping relies on particles being able to accelerate the gas towards Keplerian speed*

Dependence on metallicity

- Particles sizes 3–12 cm at 5 AU, 1–4 cm at 10 AU
- Increase pebble abundance $\Sigma_{\text{par}}/\Sigma_{\text{gas}}$ from 0.01 to 0.03

planet
formation

Anders
Johansen

Planet
formation

Planetesimals

Streaming
instability

Metallicity

Self-gravity

Conclusions

- Clumping through streaming instabilities depends *only* on mid-plane dust-to-gas ratio (metallicity), *not* on absolute column density
- However, metallicity is not a constant of a given protoplanetary disc

Protoplanetary discs can obtain critical metallicity by:

- 1 starting out with high metallicity
⇒
- 2 photoevaporating the gas
⇒
- 3 transport solids radially
⇒

Low and high metallicity planet formation

High metallicity systems

- Planet formation is rapid
- Lots of time to accrete gas
- Moderate mass planets migrate and become hot Jupiters

Solar (or lower) metallicity systems

- Planet formation triggered by photoevaporation
*(Throop & Bally 2005;
Alexander & Armitage 2007)*
- Little gas when planets form, so gas giants rare and no strong migration

Planetesimal
growth and
planet

Anders
Johansen

Planet
formation

Planetesimals

Streaming
instability

Metallicity

Self-gravity

Conclusions

Low and high metallicity planet formation

High metallicity systems

- Planet formation is rapid
- Lots of time to accrete gas
- Moderate mass planets migrate and become hot Jupiters

Solar (or lower) metallicity systems

- Planet formation triggered by photoevaporation
(Throop & Bally 2005; Alexander & Armitage 2007)
 - Little gas when planets form, so gas giants rare and no strong migration
- ⇒ Predict **fewer close in planets** in low metallicity systems and that **low mass planets can form** around low metallicity stars
- ⇒ **Need better statistics** of low metallicity systems and low mass planets

Planetesimal
growth and
planet
formation

Anders
Johansen

Planet
formation

Planetesimals

Streaming
instability

Metallicity

Self-gravity

Conclusions

Low metallicity planets

Santos et al. (A&A accepted): monitored 100 metal poor stars for planets.

- ⇒ Three planets found
- ⇒ All three planets orbit the most metal rich stars of the sample
- ⇒ *No hot Jupiters* ($a = 1.76, 1.78, 5.5$ AU)

Planetesimal growth and planet formation

Anders Johansen

Planet formation

Planetesimals

Streaming instability

Metallicity

Self-gravity

Conclusions

Low metallicity planets

Santos et al. (A&A accepted): monitored **100 metal poor stars** for planets.

- ⇒ Three planets found
- ⇒ All three planets orbit the most metal rich stars of the sample
- ⇒ *No hot Jupiters* ($a = 1.76, 1.78, 5.5$ AU)

This is a spectacular confirmation that metallicity matters even for systems of intrinsically low metallicity

Planetesimal
growth and
planet
formation

Anders
Johansen

Planet
formation

Planetesimals

Streaming
instability

Metallicity

Self-gravity

Conclusions

Conclusions

Clumping through streaming instability relevant because:

- ① Based on first principles hydrodynamical calculations
- ② Allows formation of planetesimals from pebbles and rocks
- ③ Efficiency depends very strongly on metallicity and increases sharply above solar metallicity
- ④ Can be triggered by photoevaporation, opening a new mode of planet formation around metal poor stars

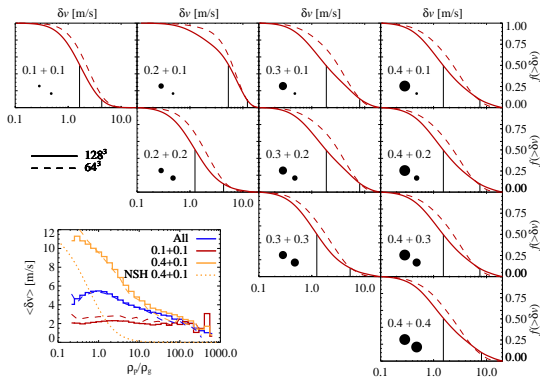

(Johansen, Youdin, & Mac Low 2009)

Collision speeds

Relative speeds of particles measured in single grid cells:

- Typical collision speed 2–5 m/s
- Only 5% of collisions faster than 10 m/s
- Collision speed in dense clumps below 2 m/s

Conclusions

- How do cm-sized pebbles and rocks form out of dust grains?
(Brauer et al. 2008; Zsom et al. 2010)
- How do pebbles survive radial drift in low metallicity discs?
(Takeuchi & Lin 2002; Brauer et al. 2007)
- What is the role of collisional fragmentation and coagulation during gravitational collapse
- What is the relative role of small scale turbulent concentrations and large scale streaming instabilities?
(Cuzzi et al. 2008; John Chambers's talk at this meeting)
- What is the size spectrum of newly formed planetesimals?
Morbidelli et al. 2009: Asteroids were born big
Core accretion and certain debris discs: Planetesimals should be small
