Invisible  
Exotic  
Hidden valley

X

# Introduction

- The Higgs width is very narrow
  - 1000x less than the W,Z
  - Plus the coupling is unique
  - There could be unknown weakly coupled particles in Higgs decay.
- The analyses discussed here are largely Higgs decay studies
- They benefit from the increase in Higgs  $\sigma$  at 13TeV
  - But with a factor 2 or 3
  - So 2015 data is relatively minor c//f 2012
- Only one result is shown based on 2015 data.

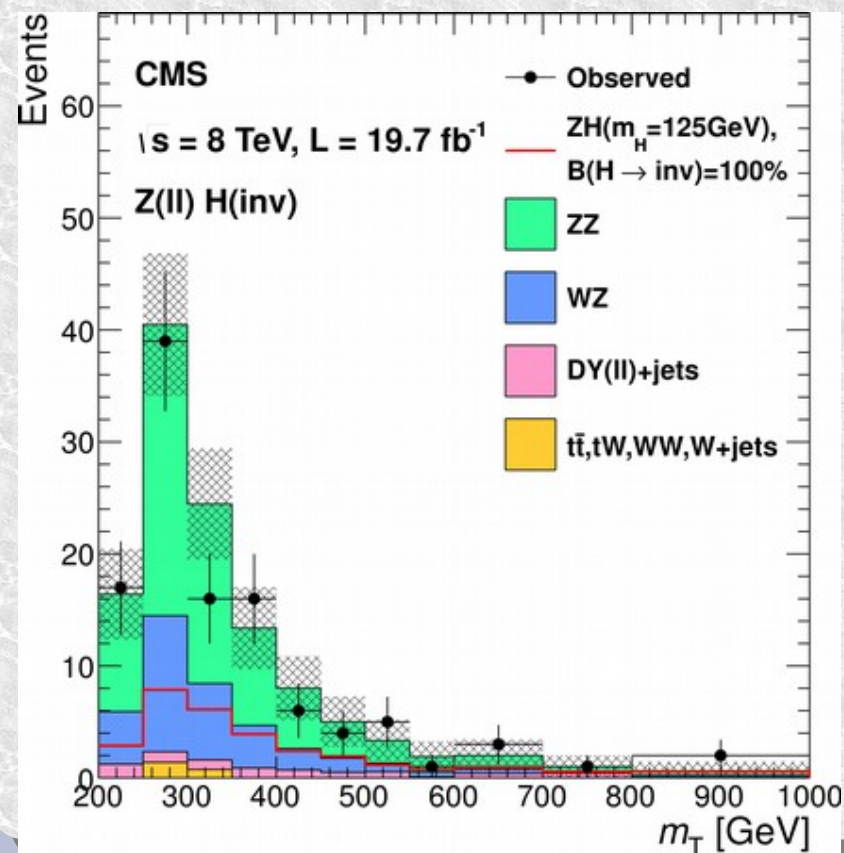

# Higgs to invisible: direct

- Dark matter is the most obvious target
- Direct observation means tagging a Higgs production along with the invisible decay
  - ggF is patently impossible
    - i.e. someone should work on it!
  - ttH has been suggested in phenomenology, but no experimental results
  - VH gives a clean experimental signature but low rate
    - $Z \rightarrow \ell\ell$  or  $W/Z \rightarrow qq$
  - VBF gives the best LHC results

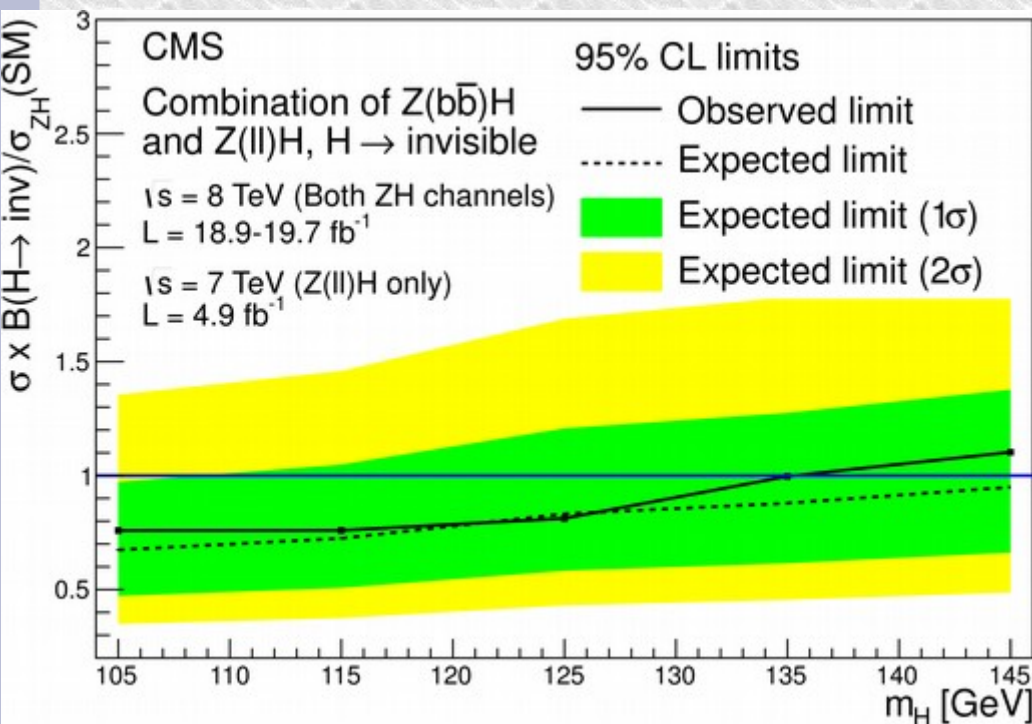

# ZH $\rightarrow$ invisible

- Z  $\rightarrow$  ll gives clean signal and easy trigger
  - Irreducible background of ZZ  $\rightarrow$  lluu dominates
  - Similar kinematics of signal and background
  - Low MET threshold helps to maximise rate

# ZH $\rightarrow$ $\ell\ell$ +invisible results

- Nothing surprising seen
- ATLAS set limits of 75% obs (62%) expected
- CMS limits: 83% obs (86% expected)

# Higgs to invisible: VBF

- VBF was essential for the  $H \rightarrow \tau\tau$  discovery

- The high-mass forward jet pair gives an improved s/b

- Tagging the jet pair allows a search for the invisible Higgs decay

- Much higher cross-section than  $ZH$
- But not as clean a tag

# VBF H to invisible

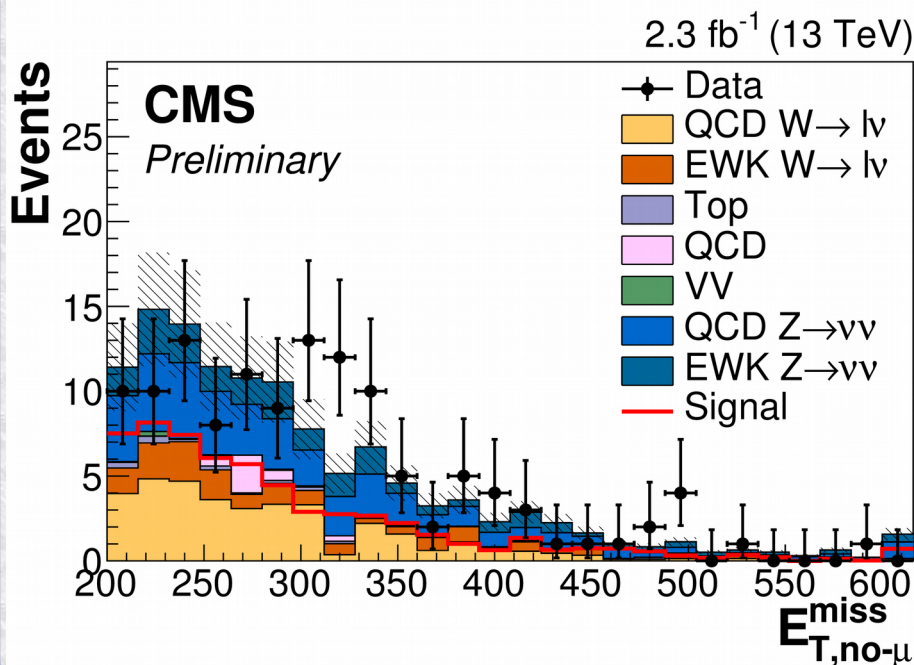

- Jet pair mass  $> 1.0\text{TeV}$  (CMS, ATLAS main signal)
- Delta eta cut on tag jets
- Observed (expected) 0.28 (0.31) in ATLAS
- Observed (expected) 0.49 (0.65) in CMS

CMS-PAS-HIG-16-0009

# CMS VBF H to invisible @ 13 TeV!

- 8 regions of  $p_T$  and jet pair mass used for VBF
- Limit set at 69% (62% expected)
  - Brings CMS combined to 32%
- Compare ratios of accepted  $\sigma$  at 13 and 8 TeV
  - Generally below PDFs – preliminary?

	8 TeV	13 TeV	ratio
$Z \rightarrow vv$	158	62	3.2
$W \rightarrow lv$	255	51	1.7
Top/qcd/V	26	6	1.9
Total	439	119	2.2
ggH	23	5.4	1.9
VBF H	273	53.5	1.7

# H to invisible summary

	ATLAS	CMS
ZH	65%	75%
VBF	28%	57%

- Clear lead for the VBF production modes
  - But in run 2 VBF may suffer from pileup
  - And it has harder systematics
    - Can we link W+jets and Z+jets as a control regions?
    - Production kinematics is not identical
- My guess is ZH will be relatively more important
- This is a vital search – we have much better evidence for DM than most many in this talk

# Higgs to invisible/BSM: indirect

ATLAS-CONF-2015-044, CMS-PAG-HIG-15-002

- Consistency of the Higgs decays in 8 parameter fit, with:
  - $\kappa_V$  constrained  $< 1$
  - Or  $BR_{BSM} = 0$
- It is impressive how insensitive fit is to this
- Upper limit on BSM decay is 0.34 @ 95% CL

# Combined invisible limit

- Direct and indirect constrains on invisible higgs are independent
- Combine for best sensitivity
- Adding visible decays moves BR limit from 25% to 23%
- Plus it is arguably less model dependent – most Brs taken from data,

# Higgs invisible v Dark Matter

- Interpret dark matter in a 'Higgs portal' model
  - Higgs only SM particle coupled to DM
- The Spin Independent is very close to this
- Strong constraints for  $m_\chi < m_H/2$ 
  - But  $\chi$  dependent

# Virtual Higgs decays

ATLAS-CONF-2015-044, CMS-PAG-HIG-15-002

- Search for BSM Higgs particle by assuming all SM but allowing arbitrary strength on Higgs loops
  - Despite early yy final hits the SM nail
- Not a trace of new particles here
  - 4<sup>th</sup> chiral fermion generations rarely considered now

Next: Visible decays

Phys. Lett. B 753 (2016) 363

# H to $\gamma(s)$ plus $E_T^{\text{miss}}$

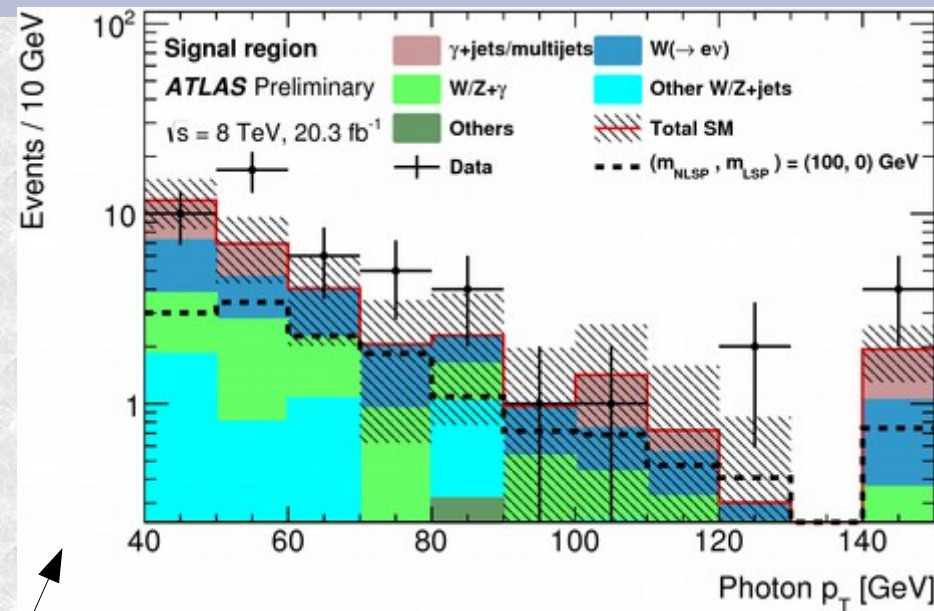

- CMS Searched for a decay to 2 gravitinos and 1/2  $\gamma$ 
  - Decay to pairs of  $\chi_1^0$  possible
- Gluon fusion selection
  - $E_T^{\text{miss}} > 40, E_t^y > 45$  GeV
  - SUSY/Mod.Indep. Variants
- ZH selection
  - $p_T^Z > 60, E_t^{\text{miss}} > 60, E_t^y > 20$  GeV
  - Study  $m_T$  of Z,  $\gamma$  &  $E_t^{\text{miss}}$
- No sign of signal,
- limits are extracted as fn of ET
- e.g. assuming light gravitino

ATLAS-CONF-2015-001

# Photon(s)+ $E_T^{\text{miss}}$ , VBF mode

- ATLAS looked in VBF selection
- Trigger on
  - $\gamma > 43 \text{ GeV}$
  - $E_T^{\text{miss}} > 60 \text{ GeV}$
- $m_{jj} > 600$ ,  $|\Delta\eta| < 4$  VBF tag
  - At most 1 central jet
  - $\Delta\phi(\gamma, E_t^{\text{miss}}) < 1.8$
  - Diphoton region also used
- Single  $\gamma$  has  $1.1\sigma$  excess
- Limits on  $H \rightarrow (\chi_1^0, \tilde{G})$  20% or looser

# Dark Photons ArXiv:1505.07645

- Dark photon, no EM coupling
  - Might mix with the Z
  - It can decay to lepton pairs
- So  $H \rightarrow \text{llll}$  might contain
  - $H \rightarrow ZZ, ZZ_D$  and/or  $Z_D Z_D$  modes
  - Target  $ZZ_D$  by using existing search: use  $m_{34}$  offshell pair
  - No evidence for  $Z_D$
  - $\text{Br}(H \rightarrow ZZ_D \rightarrow \text{llll}) < 10^{-4}$ 
    - $15 < m_{Z_D} < 55$

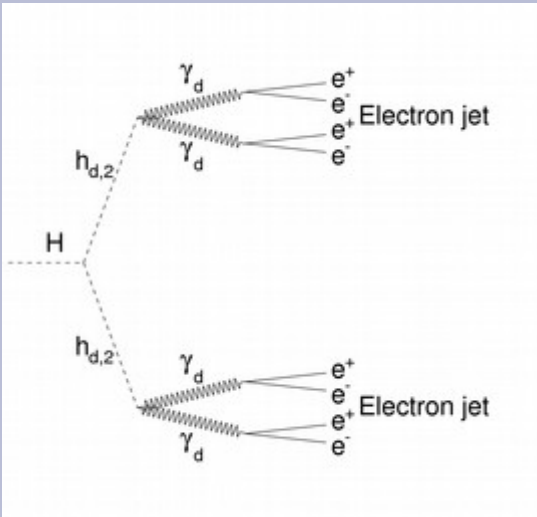

# Dark Photons: $Z_d Z_d$

- If target is pair production of  $Z_d$  start from  $4l$  search, but relax  $m_{12} \sim m_Z$
- Search mass spectrum for  $Z_D Z_D$  modes
  - 4 events with both pairs below 62.5 GeV
- Constraint of equal pair masses has just 2 events survive
  - $Br(H \rightarrow Z_d Z_d \rightarrow llll) < 3 \times 10^{-4}$ 
    - $15 < m_{Z_d} < 60$

<http://arxiv.org/abs/1302.4403>

# Higgs to electron jets

- The dark sector particles do not have to decay directly to SM
  - This model proposes a chain decay
  - With 2 or even 3 steps
  - Dark photons finally giving  $ee$  pairs.
- Analysis uses  $WH$  signature
  - $W \rightarrow l\nu$
  - Then 2 jets with  $>99\%$  EM energy
    - But large numbers of tracks
- Not re-checked with  $>2\text{fb}^{-1}$ !

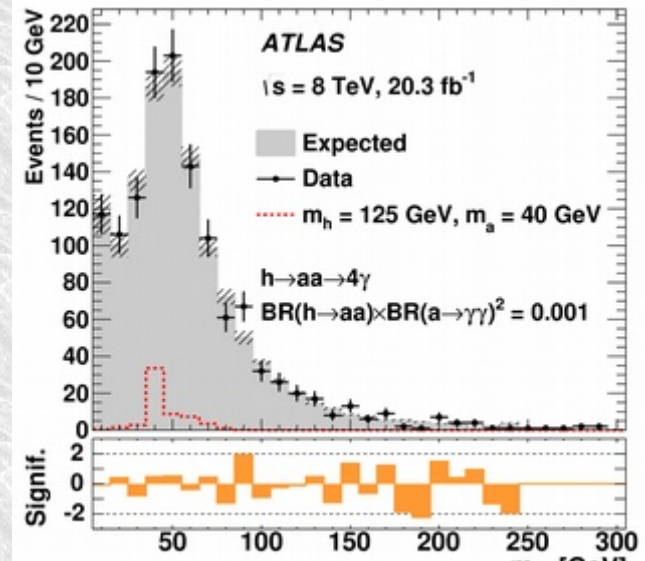

# $h \rightarrow aa \rightarrow \gamma\gamma\gamma\gamma$

arXiv:1509.05051v1

- A light nMSSM  $a$  might be produced in  $h \rightarrow aa$ 
  - With  $a \rightarrow \gamma\gamma$  a possible signature
- Select 3 photons
  - $p_T > 17$  GeV for lowest
  - Gives efficient signal reconstruction
    - 4<sup>th</sup> photon likely soft
- Total 3 $\gamma$  rate sets limits
  - Improve using  $m_{23}$  and vary  $m_a$
  - $\text{Br}(H \rightarrow aa) * \text{Br}(a \rightarrow \gamma\gamma)^2$  below  $10^{-3}$
- Is it worth trying 4 photons?

# $h \rightarrow aa \rightarrow \mu\mu\mu\mu$ [arXiv:1506.00424](https://arxiv.org/abs/1506.00424)

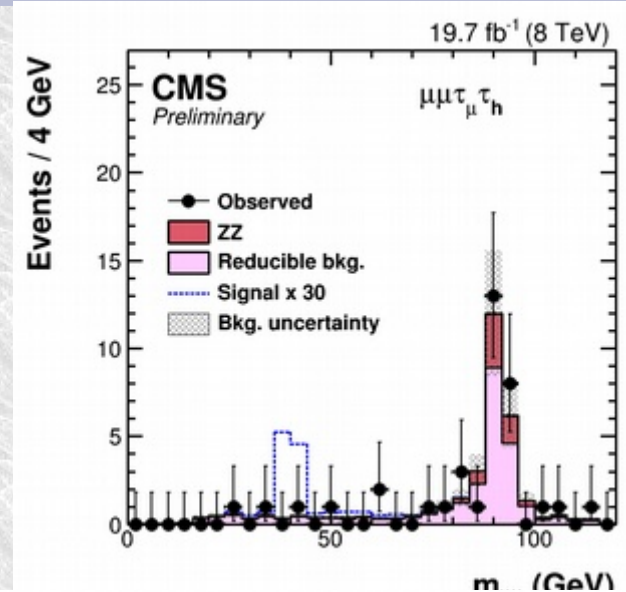

- CMS consider  $a \rightarrow \mu\mu$
- In  $2m_\mu < m_a < 2m_\tau$  window
- No equal mass events

- Limits have little dependence on  $m_a$

# $h \rightarrow aa \rightarrow \mu\mu\tau\tau$

- If  $m_a > 2m_\tau$  the  $\tau$  decay opens
- Analysis uses good  $\mu\mu$  mass to identify peak
  - $\mu p_T > 18$  (1<sup>st</sup>) & 5-9 (2<sup>nd</sup>)
- Identify  $\tau$  in e/ $\mu$ /had modes
  - $p_T > 5-15$  GeV
- 19 events observed, 20 expected
- Older results looked for 4-tau mode – no sign of signal

# Combining $a \rightarrow \mu\mu$ and $a \rightarrow \tau\tau$

- Combination needs relative rate
  - Here assume given by mass
- Upsilon region is covered by  $4\tau$
- $J/\psi$  and 15-20 not covered
- $\mu\mu b\bar{b}$  mode is also searched for

# Higgs to long-lived particles

- Hidden sector coupled very weakly to SM?
  - $H \rightarrow \pi_{\nu} \pi_{\nu}$  with long lived  $\pi_{\nu}$ 
    - Decaying to  $bb, cc, \tau$
- Here ask for decay in muon spectrometer
  - 4-7m from beam position
  - Veto jets
  - Request 2 collinear vertices
  - 0 events seen
- Limits 10% br at best
  - This is  $2\text{fb}^{-1}$  at 7 TeV
- Is metastable a priority?

# Higgs lepton flavour violation

- $H \rightarrow \mu\tau$  from CMS
  - 0/1/2 jets  $\times \tau_e/\tau_h$
- The most powerful is 0 jets  $\times \tau_e$ 
  - Also has the most significant excess
  - Shown right
- Br is  $0.84 \pm 0.38\%$

# ATLAS LFV

- $H \rightarrow \mu\tau_h$  only
  - Divided into two categories of  $mT_{<,>40}$  GeV
- They are combined in the plot right:
- Br is  $0.77 \pm 0.62\%$
- Remember CMS found the most powerful is  $0 \text{ jets} \times \tau_e$

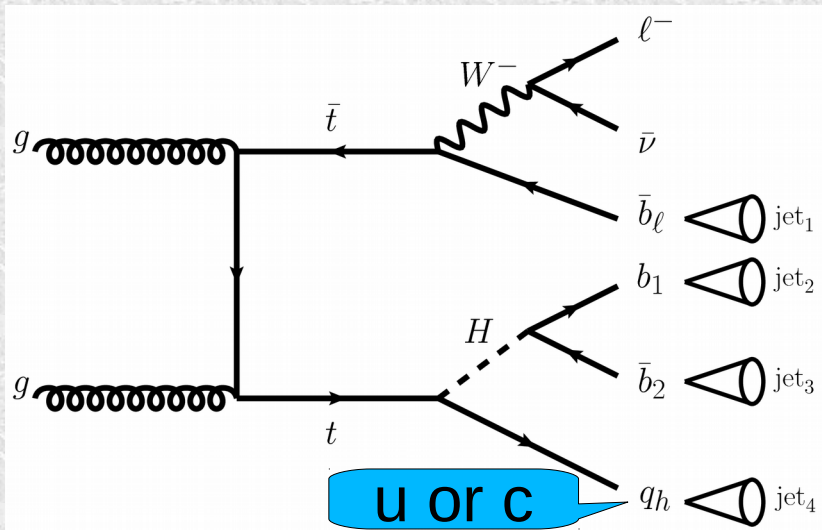

# $H \rightarrow \tau\mu$ LFV

$H \rightarrow \mu\tau$ limits	ATLAS		CMS	
	Expected	Observed	Expected	Observed
$\mu\tau_e$	n.a.	n.a.	1.32/1.66/3. 77%	2.04/2.38/3. 84%
$\mu\tau_h$	1.24%	1.85%	2.34.2.07/2. 31%	2.61/2.22/3. 68%
Combined	1.24%	1.85%	0.75%	1.51%

- Both ATLAS and CMS have excesses
  - 2.1 sigma in CMS, 1.2sigma in ATLAS
- Clearly a very interesting, but not very significant, excess

# FCNC $t \rightarrow Hq$ ; $H \rightarrow bb$

- $W \rightarrow l$  trigger
- Multiple categories, kinematic discriminant in each discriminant
- 4j, 4b has best s/b for  $t \rightarrow cH$

# FCNC top-Higgs

● Di-photon has hadronic and leptonic top selections

- Multilepton 7 categories of 2/3 leptons, 4/5 jets
- Usually a small excess

# CMS FCNC $t \rightarrow Hx$

- CMS use  $H \rightarrow \gamma\gamma$  and multilepton
  - Multiple  $E_T^{\text{miss}}$  categories used
  - Re-using  $A \rightarrow Zh$  and  $H \rightarrow hh$  search

Channel	$E_T^{\text{miss}}$ (GeV)	$N_b$	Obs.	Exp.	Sig.
$\gamma\gamma\ell$	(50, 100)	$\geq 1$	1	$2.3 \pm 1.2$	$2.88 \pm 0.39$
	(30, 50)	$\geq 1$	2	$1.1 \pm 0.6$	$2.16 \pm 0.30$
	(0, 30)	$\geq 1$	2	$2.1 \pm 1.1$	$1.76 \pm 0.24$
	(50, 100)	0	7	$9.5 \pm 4.4$	$2.22 \pm 0.31$
	(100, $\infty$ )	$\geq 1$	0	$0.5 \pm 0.4$	$0.92 \pm 0.14$
	(100, $\infty$ )	0	1	$2.2 \pm 1.0$	$0.94 \pm 0.17$
	$lll$ (OSSF1, below-Z)	(50, 100)	$\geq 1$	48	$48 \pm 23$
(0, 50)		$\geq 1$	34	$42 \pm 11$	$5.9 \pm 1.2$
$lll$ (OSSF0)	(50, 100)	$\geq 1$	29	$26 \pm 13$	$5.9 \pm 1.3$
	(0, 50)	$\geq 1$	29	$23 \pm 10$	$4.3 \pm 1.1$

# Combination of $t \rightarrow Hc$

$t \rightarrow Hc$	ATLAS		CMS	
	Expected	Observed	Expected	Observed
$H \rightarrow \gamma\gamma$	0.51%	0.79%	0.81%	0.69%
$H \rightarrow$ multilepton	0.54%	0.79%	1.17%	1.28%
$H \rightarrow bb$	0.42%	0.56%	n.a.	
Combined	0.25%	0.46%	0.65%	0.56%

- Small excess in ATLAS

- $< 2\sigma$

- Not confirmed in CMS

- Though less sensitive

# Conclusions: no new physics

## • BSM couplings analyses

- $H \rightarrow \text{BSM}$   $\text{Br} < 34\%$  **ATLAS+CMS**,  $\kappa_V < 1$  assumed
  - Loops with virtual particles ( $gg \rightarrow H, H \rightarrow \gamma\gamma$ ) good to 10%
- $H \rightarrow \text{Invisible}$   $\text{Br} < 25\%$  direct (23% in combination)

## • Non-SM couplings of the $H_{125}$ searched for:

- $\text{Br}(H \rightarrow Z_{(d)} Z_d \rightarrow \text{llll}) < (3x)10^{-4}$  for  $15 < m_{Z_d} < 55$
- $\text{BR}(H \rightarrow X \rightarrow \gamma_d) < 30\text{-}40\%$  for  $m_{\gamma_d} = 100\text{MeV}$ : electron jets
- $\text{Br}(H \rightarrow aa) * \text{Br}(a \rightarrow \mu\mu)^2$  below  $10^{-4}$  (to  $10^{-6}$ !) for  $0.2 < m_a < 60$
- $\text{Br}(H \rightarrow aa) * \text{Br}(a \rightarrow \gamma\gamma)^2$  below  $10^{-3}$
- $H \rightarrow \pi_V \pi_V$  long-lived are  $< 50\%$   $\text{Br}$   $20 < m_\pi < 40$   $2 < c\tau < 12\text{m}$ 
  - 10% at best points
- $H \rightarrow \chi G / \chi\chi \rightarrow G\gamma(\gamma)$   $\text{Br} < 10\%$   $1 < m_\chi < 120$

## • Flavour changing analyses interesting

- $H \rightarrow \mu\tau$ ,  $t \rightarrow Hc$  both have small excess

# Post-conclusions:

- I pray your indulgence for a few slides on
  - $\Gamma(H \rightarrow WW)$ 
    - Dependence on  $\Gamma_w$
  - ttX
    - A question on modelling

# Higgs width to W

- The Higgs decay width to off-shell dibosons is to LO given by: [Djouadi's Anatomy](#)

$$\Gamma(H^0 \rightarrow V^* V^*) = \frac{1}{\pi^2} \int_0^{M_{H^0}^2} \frac{dq_1^2 M_V \Gamma_V}{(q_1^2 - M_V^2)^2 + M_V^2 \Gamma_V^2} \int_0^{(M_{H^0} - Q_1)^2} \frac{dq_2^2 M_V \Gamma_V}{(q_2^2 - M_V^2)^2 + M_V^2 \Gamma_V^2} \Gamma_0$$

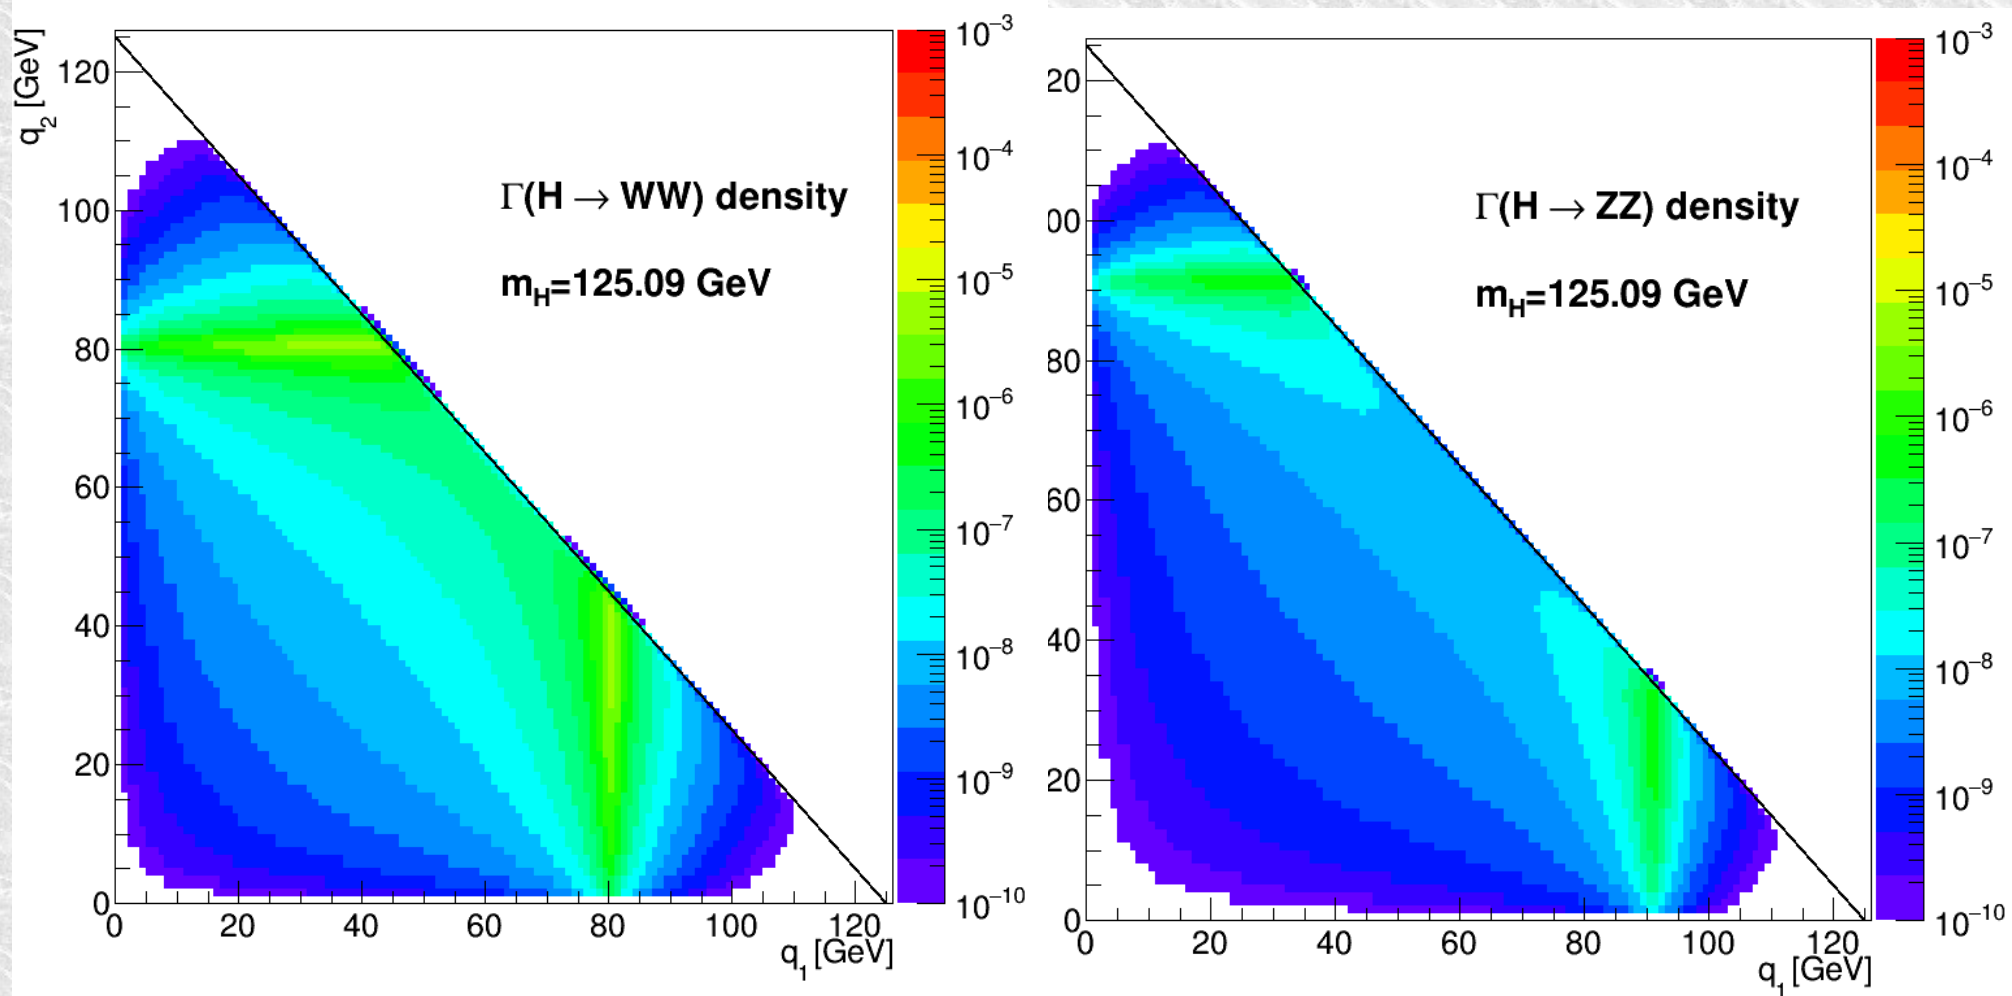

- For the case of one on shell and one off shell this become approximately proportional to one power of the width.
  - Thus the Br  $H \rightarrow WW$  is proportional to the W boson width
  - This is currently known to 2%
  - Not totally negligible in analysing Higgs width

# $\Gamma_{WW}(q_1, q_2)$ for $m_H = 100, 200$

# $\Gamma_{WW/ZZ}(q_1, q_2)$ for $m_H = 125.09$

# How to interpret?

- Integrate to get the total width:
  - $\Gamma_{WW}|_{10} = 0.941 \text{ MeV}$  at 126
  - c/f 0.974 MeV in YR3 at the same mass
  - Agreement to 3% (2% for ZZ)
- Now calculate width at 125.09:
  - $\Gamma_{WW} = 0.853 \text{ MeV}$  at 125.09
- BR(H  $\rightarrow$  WW) must sum over all Brs
  - And LHC does not measure Brs anyway
  - So find  $\Gamma_{WW}/\Gamma_{ZZ} = \text{BR}(WW)/\text{BR}(ZZ)$
  - $\text{BR}/\text{BR}|_{10} = 7.99$  (c/f 8.07 in YR 3)
- Data ratio is in the LHC CONF on couplings.
  - So find how Br varies with  $\Gamma_W$

# BR ratio v W width

- Quadratic for low mass Higgs, const for 200 Gev
  - Due to 2 or 0 of shell W bosons

# BR ratio v W width

- Linear for  $m_H = 125.09$

- One W on shell, the other off.

- Use measured

$$BR(WW)/BR(ZZ) = 6.8^{+1.7}_{-1.3}$$

- Extract

$$\Gamma_W = 1.8^{+0.4}_{-0.3} \text{ GeV}$$

- This can be compared with  $2.085 \pm 0.042$  world average

- Factor 10 worse
- But errors will improve

# Systematic errors

- Few parametric ingredients:
  - $m_Z$
  - $m_W$
  - $m_H$
  - $\Gamma_Z$
  - $\Gamma_H$
- None of them contribute significantly
  - Biggest is  $\Gamma_Z$  which is known 20x better than  $\Gamma_Z$ .
- Theoretical uncertainty on  $\Gamma(H \rightarrow WW)$  extraction is 0.5%
  - Again, negligible.

# Conclusion

- The W boson width should not be ignored in Higgs boson coupling studies
- First LHC measurement of the W boson width!

$$\Gamma_W = 1.8_{-0.3}^{+0.4} \text{ GeV}$$

- From Higgs branching ratios
- Assumes SM couplings
- I am asking Higgs/Pc whether I can publish
- Errors comparable to any other experiment
  - Factor 10 off world average
  - But will improve with time
- A proper measurement of the W width is needed to exploit Higgs measurements fully.

## $tt + X$

- Many searches look for  $tt$  plus more
  - $ttV$ , SUSY, vector like quarks,  $ttH$  all have searches where you add leptons or  $b$  quarks to a  $tt$  system.
  - Modelling is complex, but e.g.  $ttbb$  is known at NLO
- So can we confidently predict SM backgrounds to such searches?

# $t\bar{t}$ plus jets

CMS-PAS-TOP-16-008

- Excellent to have high quality data on this fast
- But some work on understanding still...

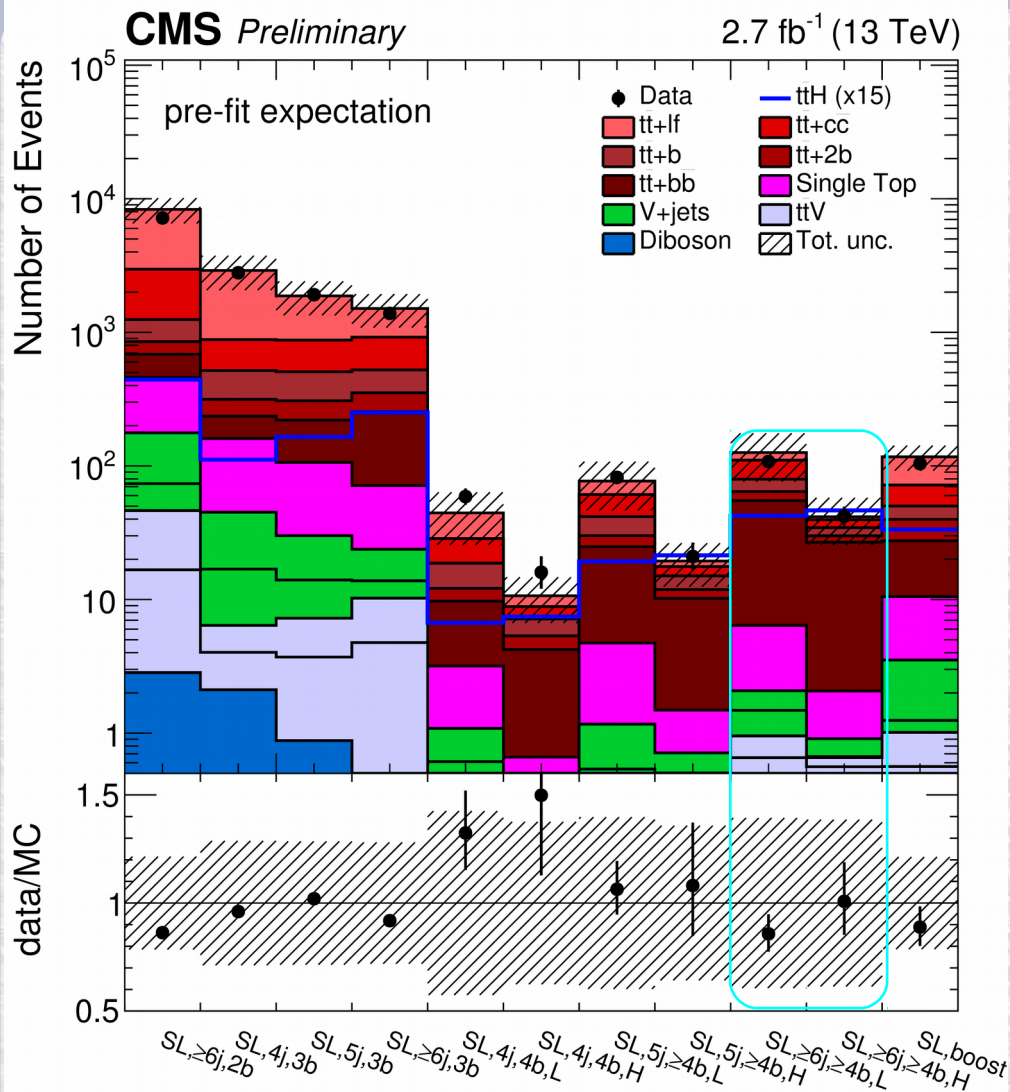

# ATLAS VLQ v CMS ttH

- Both analyses select 1 lepton and at least 4 jets, at least 2 b tagged
- Examine categories by numbers of jets, b jets and boosted jet candidates
- ATLAS has problems with ttbb rates
- See 120% - 190% of MC in these regions
- Meanwhile CMS sees expected rate!
  - Modelling of this states is complicated

# ATLAS VLQ v CMS ttH

# VLQ – 2: 6j4b pre/post fit

● Factor 2 increase in  $t\bar{t}b\bar{b}$  component to fit data

# ttH - multilepton

● Excess for 5 jets+ in both years?

# ttH

## ● Multilepton ttH analysis in 2012

- This channel is 3-leptons and one b jet
- Plot shows Njets  $p_T > 25\text{GeV}$
- Again, factor 2 increase for 5+ jets

# tt modelling

- ttbb and tt+leptons are complex systems to model
- tt+jets overall seems reasonably defined
- ttbb:
  - At 13 TeV in CMS looks plausibly modelled
  - In ATLAS there is a factor 2 discrepancy
- Can we treat ttbb shape and rate as independent?
- 3-leptons plus a b
  - Events with 5 or 6 jets have excesses at 8 and 13 TeV in CMS and 8 TeV in ATLAS.
  - Remember: tt+4 jets modelling gets tricky
