GRAVITATIONAL MICROLENSING BY DOUBLE STARS AND PLANETARY SYSTEMS

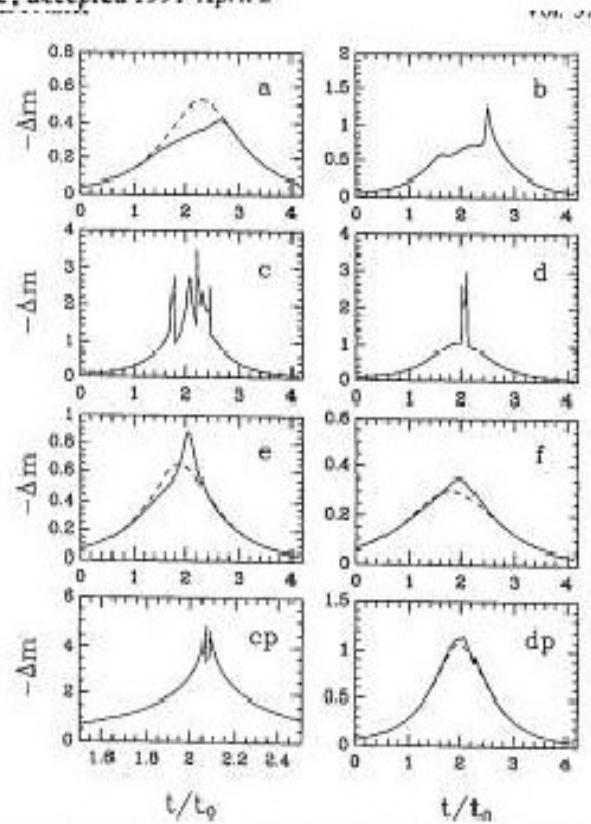

SHUDE MAO AND BOHDAN PACZYŃSKI

Princeton University Observatory, Princeton, NJ 08544

Received 1991 March 12; accepted 1991 April 2

1.—Geometry of microlensing by a binary, as seen in the sky. The primary star of  $1 M_{\odot}$  is located at the center of the figure, and the secondary of  $0.001 M_{\odot}$  is located on the right, on the Einstein ring of the primary. The radius of the ring is 1.0 mas for a source located at a distance of 8 kpc from the lens at 4 kpc. The two complicated shapes around the primary are

the lens. The effect is strong even if the companion is a planet. A massive search for microlensing of the Galactic bulge stars may lead to a discovery of the first extrasolar planetary systems.

## Planetary Caustics

DISCOVERING PLANETARY SYSTEMS THROUGH GRAVITATIONAL MICROLENSES

ANDREW GOULD AND ABRAHAM LOEB

Institute for Advanced Study, Princeton, NJ 08540

Received 1991 December 26; accepted 1992 March 9

### 5. OBSERVATIONAL REQUIREMENTS

Two distinct steps are required to observe a planetary system by microlensing. First, one must single out a disk star which happens to be microlensing a bulge star. Second, one must observe this star often enough to catch the deviation in the light curve due to the planet. The first step involves the observation of millions of bulge stars on the order of once per day. The second step involves the observation of a handful of stars many times per day. In the following we give a rough outline of what is required for each of these steps.

While observations from one site would be useful, there are advantages to be gained by observing from several sites. First, two telescopes that were totally committed. Third, in view of the fleeting nature of the events, it would seem prudent to build in some redundancy in case of bad weather at a particular site. Thus, the optimal scheme would employ, say, a dozen telescopes. Each of these would be committed to carry out two observations per night. During the near-December season,

# Satellite Parallaxes (Panacea?)

ON THE POSSIBILITY OF DETERMINING THE DISTANCES  
AND MASSES OF STARS FROM THE GRAVITATIONAL  
LENS EFFECT

*S. Refsdal*

(Communicated by Professor S. Rosseland)

(Received 1966 June 6)

## *Summary*

It is shown that the distance and the mass of a star which acts as a gravitational lens can be determined if the lens effect can be observed from the Earth and from at least one distant space observatory. The distance from the Earth to the space observatory will usually have to be of the order of 5% of one astronomical unit or more.

# Conclusions

- Microlens Mass Measurements now “common”
  - But only for nearby lenses
- Spitzer delivering dozens of  $\mu$ lens parallaxes
  - Longer program-> Galactic Planet Distribution
- Multi-Plexing for Mass Production of Microlens Parallaxes (**MP**)<sup>3</sup>
  - Kepler can measure Free-Floating Planets
- WFIRST mlensing -> Planets +++
  - Astrometry: 100 times better than Gaia
  - Asteroseismology of 1,000,000 stars
  - Precision orbits for 5000 ultra-faint KBOs
