“WE ALSO DO RESEARCH”

Hadronic parity nonconservation is *tiny*.  
Need either *very* sensitive measurements...  
..or a good amplification!

$$\text{PNC amplitude} = \frac{\langle \psi_- | \hat{H}_{PNC} | \psi_+ \rangle}{E_- - E_+}$$

(in 1<sup>st</sup> order perturbation theory)

SAN DIEGO STATE  
UNIVERSITY

“WE ALSO DO RESEARCH”

Hadronic parity nonconservation is *tiny*.  
Need either *very* sensitive measurements...  
..or a good amplification!

$$\text{PNC amplitude} = \frac{\langle \psi_- | \hat{H}_{PNC} | \psi_+ \rangle}{E_- - E_+}$$

(in 1<sup>st</sup> order perturbation theory)

So... look for nearby  
parity doublets!

UNIVERSITY

“WE ALSO DO RESEARCH”

Barnes *et al* PRL **40**, 840, 1980

Circular polarization  $\sim (-0.7 \pm 2.0) \times 10^{-3}$

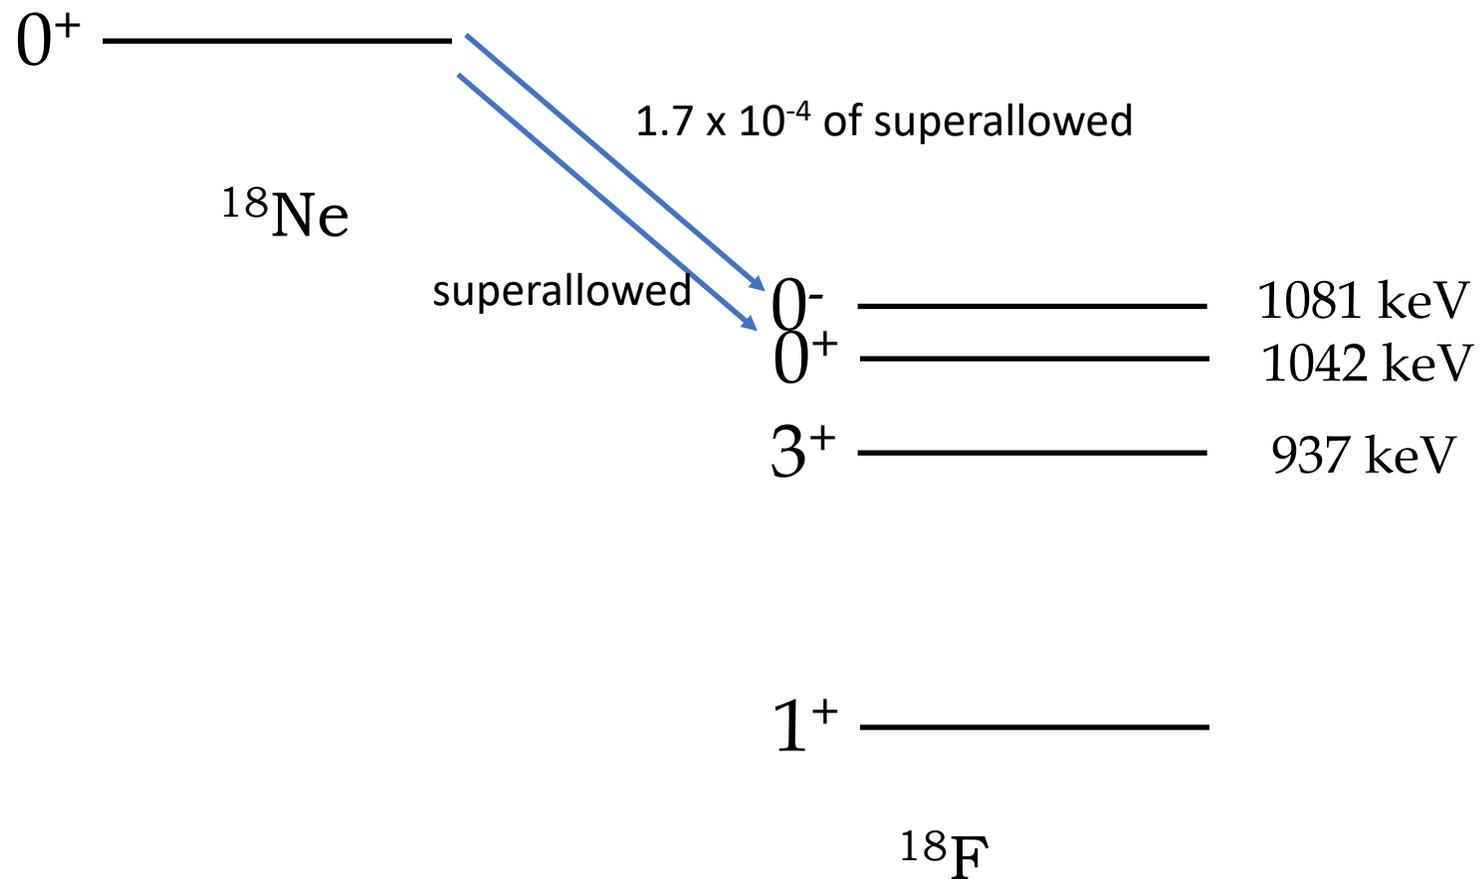

$^{18}\text{F}$

SAN DIEGO STATE  
UNIVERSITY

“WE ALSO DO RESEARCH”

Adelberger *et al* PRL **46**, 695, 1981

$^{18}\text{F}$

g.s. is  $1^+$ ; low-lying  $0^+, 0^-$  separated by only 39 keV!  $\rightarrow$  mixing in  $\gamma$  decay

2-body current tricky to compute, although with new *ab initio* methods ( $\chi$  EFT or lattice QCD) now better.

Old idea: relate 2-body  $0^-$  operator to 1-body ops  $\vec{\sigma} \cdot \vec{r}$ ,  $\vec{\sigma} \cdot \vec{\nabla}$  ( $1^{\text{st}}$  forbidden axial vector (Gamow-Teller))

See Haxton PRL **46**, 698 (1981), Haxton +CWJ, PRL **65**, 1325 (1990)

# Configuration-interaction shell model

Flexible microscopic model with *ab initio* foundations

*“Diagonalize once and get lots of eigenvalues”* --KN

SAN DIEGO STATE  
UNIVERSITY

“WE ALSO DO RESEARCH”

# Configuration-interaction shell model

Flexible microscopic model with *ab initio* foundations

Basic idea: (1) compute matrix elements of modern two-body PNC operators and check robustness (e.g., with model space, interaction), and (2) check proportionality hypothesis between 2- and 1-body operators

## THE BASIC PROBLEM

The basic *science question* is to model detailed quantum structure of many-body systems, such the structure of an atomic nucleus.

SAN DIEGO STATE  
UNIVERSITY

“WE ALSO DO RESEARCH”

To answer this, we solve *Schrödinger's equation*:

$$\hat{\mathbf{H}}|\Psi\rangle = E|\Psi\rangle$$

- \*  $\mathbf{H}$  is generally a very large matrix – dimensions up to  $10^{10}$  have been tackled.
- \*  $\mathbf{H}$  is generally very sparse.
- \* We usually only want a few low-lying states

# THE BASIC PROBLEM

SAN DIEGO STATE  
UNIVERSITY

“WE ALSO DO RESEARCH”

$$|\Psi\rangle = \sum_{\alpha} c_{\alpha} |\alpha\rangle \quad H_{\alpha\beta} = \langle\alpha|\hat{\mathbf{H}}|\beta\rangle$$

$$\sum_{\beta} H_{\alpha\beta} c_{\beta} = E c_{\alpha} \quad \text{if} \quad \langle\alpha|\beta\rangle = \delta_{\alpha\beta}$$

so we use the matrix formalism

$$\hat{\mathbf{H}}|\Psi\rangle = E|\Psi\rangle$$

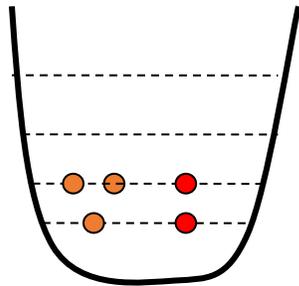

SAN DIEGO STATE  
UNIVERSITY

“WE ALSO DO RESEARCH”

Nuclear Hamiltonian: 
$$\hat{H} = \sum_i -\frac{\hbar^2}{2M} \nabla_i^2 + \sum_{i<j} V(r_i, r_j)$$

Solve by diagonalizing  $\mathbf{H}$  in a basis of many-body states.

The many-body states are *Slater determinants*, or anti-symmetrized products of single-particle wfns.

The single-particle states are defined by a single-particle potential  $U(r)$  (such as harmonic oscillator or Hartree-Fock)

At this point one generally goes to occupation representation:

$$\hat{H} = \sum_i \varepsilon_i \hat{a}_i^\dagger \hat{a}_i + \frac{1}{4} \sum_{ijkl} V_{ijkl} \hat{a}_i^\dagger \hat{a}_j^\dagger \hat{a}_l \hat{a}_k$$

single-particle energies

two-body matrix elements

Maria Mayer

When running a fermion shell model code (e.g. MFD, **BIGSTICK**), one enters the following information:

(1) The single-particle valence space (such as *sd* or *pf*); assumes inert core

(2) The many-body model space (number of protons and neutrons, truncations, etc.)

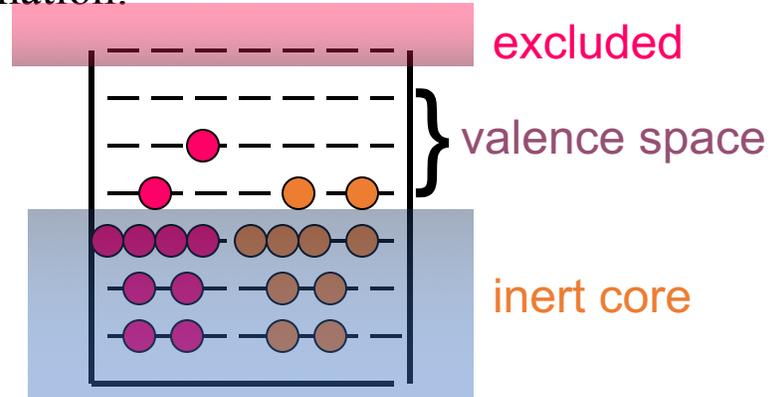

(3) The interaction:

single-particle energies

and

two-body matrix elements

$V_{JT}(ab,cd)$

Interaction File

SAN DIEGO STATE  
UNIVERSITY

“WE ALSO DO RESEARCH”

## *Not your grandfather's shell model*

NN data -> high precision description of nuclear forces

e.g. Argonne potential, chiral EFT, phase-equivalent potentials (JISP, Daejeon)

Note: these all agree on phase shifts, deuteron binding = on shell matrix elements  
Differ on off-shell matrix elements -> three-body forces

SAN DIEGO STATE  
UNIVERSITY

“WE ALSO DO RESEARCH”

## *Not your grandfather's shell model*

NN data -> high precision description of nuclear forces

Unitary transformations (“similarity renormalization group”)

”soften” the hard core = reduce coupling between low and high momentum

These induce additional three (and four) body forces.

Note: main effect is to shift energies down [CWJ, PLB **774**, 465 (2017) ]

SAN DIEGO STATE  
UNIVERSITY

“WE ALSO DO RESEARCH”

## *Not your grandfather's shell model*

NN data -> high precision description of nuclear forces

Unitary transformations “soften” the hard core

No-core shell model space (all particles active) reduces intruder states  
(some cluster states still intruders, e.g. Hoyle state in  $^{12}\text{C}$ ,  $0^+_2$  state in  $^{16}\text{O}$ )

SAN DIEGO STATE  
UNIVERSITY

“WE ALSO DO RESEARCH”

## *Not your grandfather's shell model*

NN data -> high precision description of nuclear forces

Unitary transformations “soften” the hard core

No-core shell model space (all particles active) reduces intruder states

Modern high performance computing allows us to go to much larger spaces.

1989: 4p-4h calculation of  $^{16}\text{O}$  dim  $\sim 1.2$  million bases, “state of the art”

SAN DIEGO STATE  
UNIVERSITY

# The BIGSTICK shell-model code, free and open-source

The Hamiltonian matrix elements are “factorized” and reconstructed on-the-fly. See CWJ, Ormand, and Krastev, *Comp. Phys. Comm.* **184**, 2761 (2013)

Has both OpenMP and MPI parallelization;  
Runs on laptops up through supercomputers.  
Both phenomenological and no-core shell model  
spaces and interactions.

A big concern I have: correct 4p-4h states in wave functions.

# $^{18}\text{F}$ shell model calculations

SAN DIEGO STATE  
UNIVERSITY

“WE ALSO DO RESEARCH”

A big concern I have: correct 4p-4h states in wave functions.

Near the p-sd boundary, we see strong 4p-4h correlations. These include the famous Hoyle state in  $^{12}\text{C}$  and the analogous  $0^+_2$  state at 6 MeV in  $^{16}\text{O}$ .

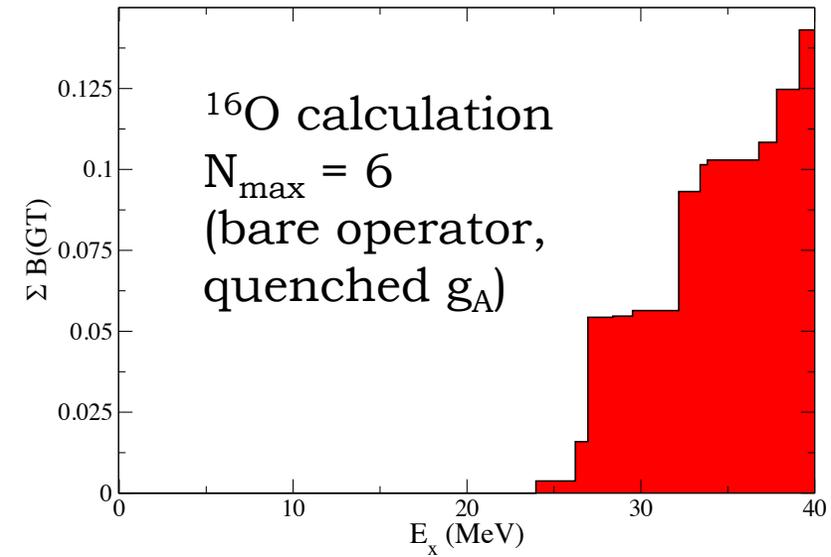

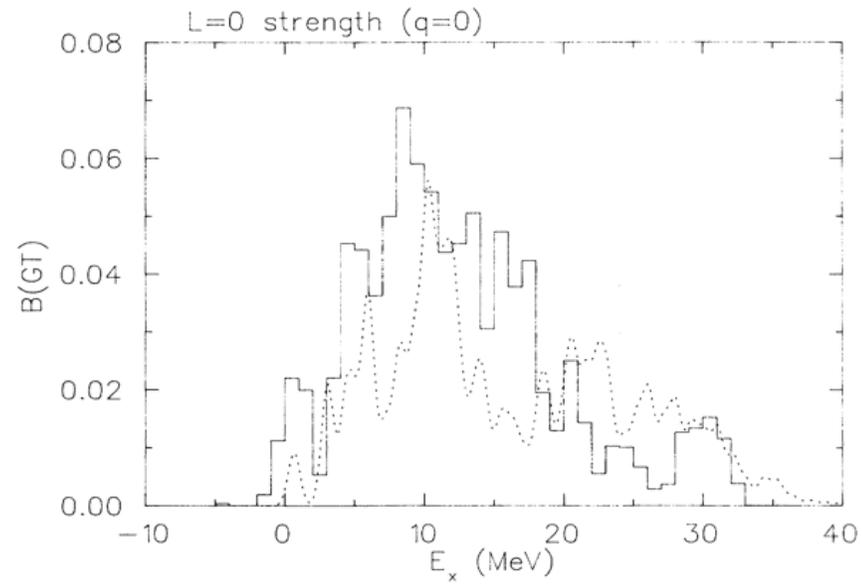

No-core shell model calculations have these too high in the spectra. These probably cannot be arrived at by brute force.

It's not clear what effect these correlations will have on PNC matrix elements.

Can test by artificially lowering 4p-4h states in  $^{12}\text{C}$ ,  $^{16}\text{O}$  by adjusting single-particle energies, monopole terms.

# Conclusions

SAN DIEGO STATE  
UNIVERSITY

“WE ALSO DO RESEARCH”

We're in a new 'golden age' of nuclear structure calculations, powered by new techniques and supercomputers!

Can do rigorous *ab initio* calculations of many nuclear properties, especially in the lower *p*-shell.

But additional challenges arise in the upper *p*-shell and lower *sd*-shell, specifically the alpha-particle clusters seen in the Hoyle state and analogs in nearby nuclei.
