

# The Puzzle of Superconductivity at $T_c \approx 22$ K in Ba(or Sr)Fe<sub>2</sub>As<sub>2</sub> Exposed to *Reactive Gases*

G. N. Tam, J. S. Kim, B. Demaske, S. Phillpot, H. Maruyama, J. Nino, and G. R. Stewart  
Department of Physics, University of Florida, Gainesville, FL 32611

Just to set the stage,  $\text{BaFe}_2\text{As}_2$  exposed to several reactive gases, including fluorine, shows a resistive transition to superconductivity at just over 20 K. This talk is about why?

This Behavior ( $T_c \approx 22$  K) Was First Observed<sup>1</sup> in Resistive Measurements of Thin Films of  $\text{SrFe}_2\text{As}_2$  Exposed to *Water Vapor*

1. H. Hiramatsu, T. Katase, T. Kamiya, M. Hirano and H. Hosono, Phys. Rev. B 80, 052501 (2009). (47 citations to date)

# This Behavior ( $T_c \approx 22$ K) Was First Observed<sup>1</sup> in Resistive Measurements of Thin Films of $\text{SrFe}_2\text{As}_2$ Exposed to *Water Vapor*

- Upon exposure to water vapor they measured a decrease in the c-axis lattice parameter. They considered possible intercalation of  $\text{O}_2^-$  into interstitial sites.

1. H. Hiramatsu, T. Katase, T. Kamiya, M. Hirano and H. Hosono, Phys. Rev. B 80, 052501 (2009). (47 citations to date)

In  $\text{SrFe}_2\text{As}_2$  : 2 large interstitial sites (both large enough to hold an  $\text{O}_2^-$  ion) marked by green sphere

Rather than interstitial doping, Hiramatsu, et al. also considered the possibility of creation of Sr vacancies through a reaction with the  $\text{H}_2\text{O}$  molecule to form an alkaline earth hydroxide  $\text{Sr}(\text{OH})_2$ . (Remember this for later)

## Works Related to the Hiramatsu et al. $\text{SrFe}_2\text{As}_2$ + Water Vapor Work:

- Y. Mizuguchi, K. Deguchi, S. Tsuda, T. Yamaguchi, and Y. Takano, Phys. Rev. B 81, 214510 (2010)
  - induced superconductivity in  $\text{Fe}_{0.8}\text{Te}_{0.2}\text{S}_{0.2}$  (just like  $\text{SrFe}_2\text{As}_2$  also normally not superconducting) by exposure to air containing water vapor. Speed of evolution of  $T_c$  with time “strongly enhanced” by immersion in 70 °C water. Up to 48% diamagnetic shielding.

- cause of superconductivity: since the lattice shrinks, they consider  $\text{H}^+$ ,  $\text{OH}^-$  and  $\text{O}_2^-$  as possible electron dopants. No microscopic data (e. g. XAFS) to corroborate.

## Works Related to the Hiramatsu et al. $\text{SrFe}_2\text{As}_2$ + Water Vapor Work:

- In a follow up paper (Deguchi et al., Supercond. Sci. Technol. 25, 084025 (2012)) correlated the presence of various acids in the liquids with superconductivity and suggested that – rather than electron doping – perhaps the cause of the superconductivity was removal of excess Fe from interlayer sites (not really germane to work on  $(\text{Sr},\text{Ba})\text{Fe}_2\text{As}_2$ .)

So, the question arises, what else could be reacted with the 122 (Sr,Ba)Fe<sub>2</sub>As<sub>2</sub> compounds to investigate this ~22 K superconductivity?

# $T_c \approx 22$ K in $\text{BaFe}_2\text{As}_2$ Exposed to $\text{F}_2$

Note that  $\rho \rightarrow 0$  is fairly narrow. Note also the large amount of work\* on this effect in 'as-prepared' xtals.

\*e. g. Paglione et al. as well as our group

# Focus on Fluorinated $\text{BaFe}_2\text{As}_2$ and Its Properties

## -What are the Important Questions?-

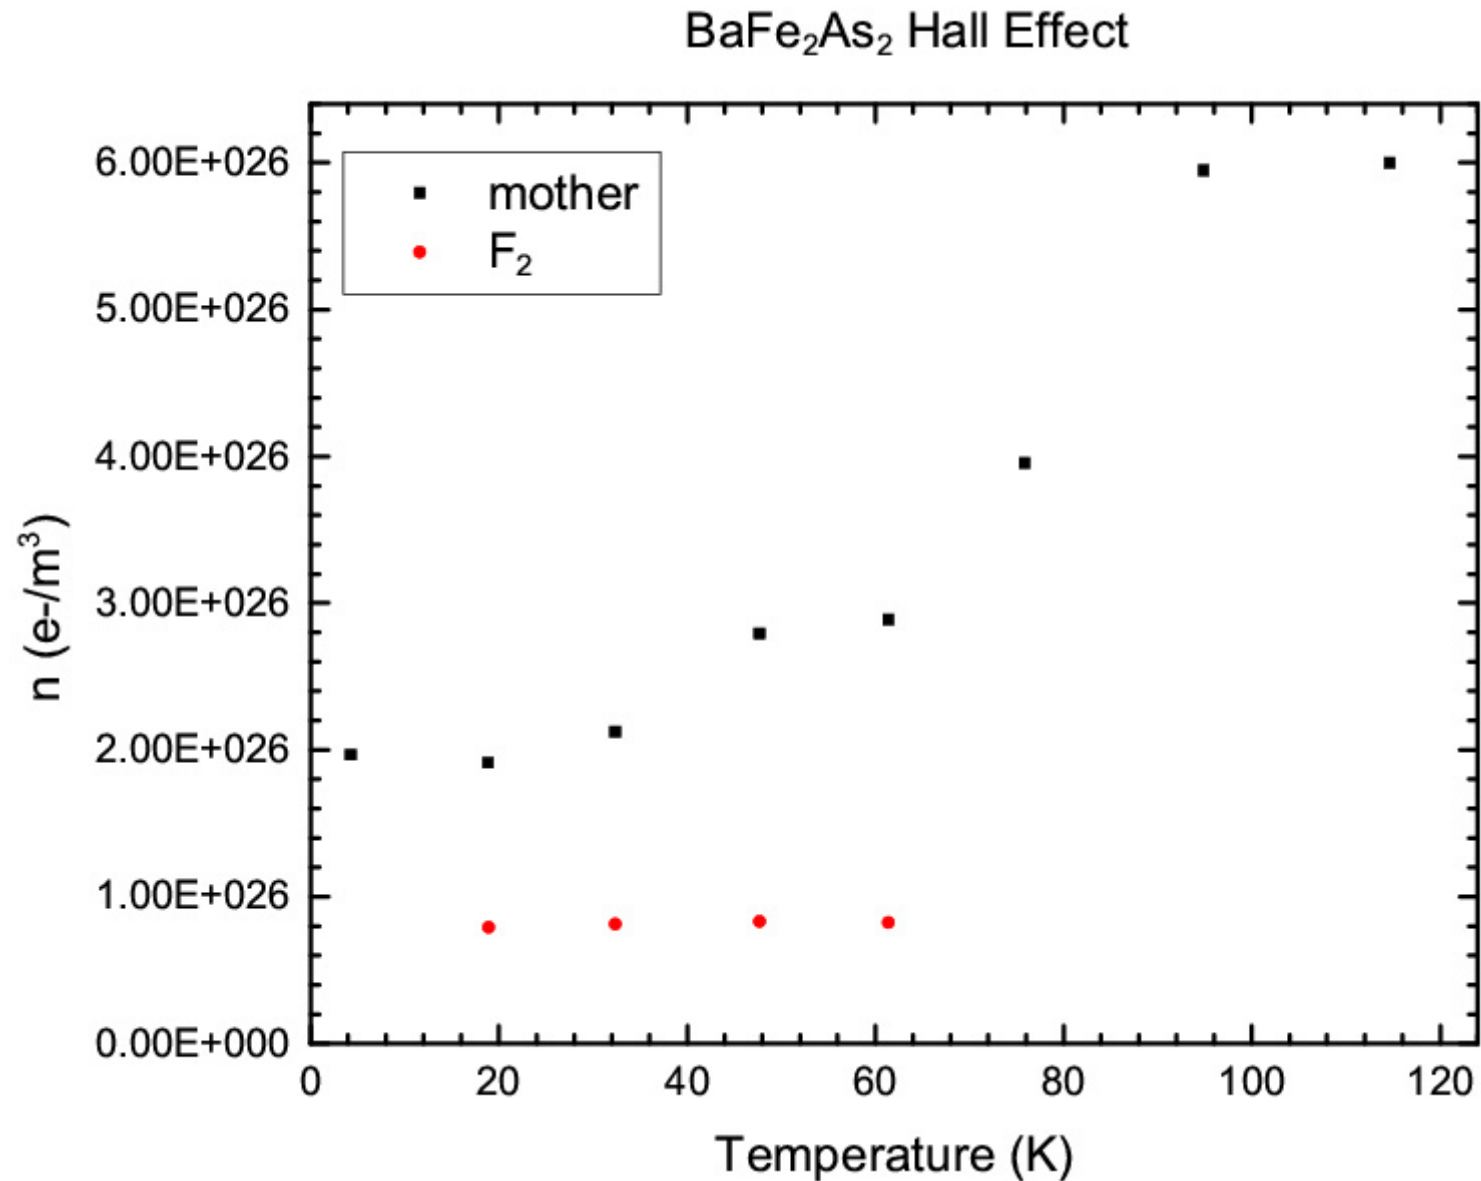

- How deep is the superconductivity?
- Any change in lattice parameters?
- Hall Effect
- X-ray Photoemission Spectroscopy: Input as to where F goes in the lattice?
- DFT calculations: where might the F be going?

# Focus on Fluorinated $\text{BaFe}_2\text{As}_2$ and Its Properties

-What are the Important Questions?-

- How deep is the superconductivity?  $5 - 10 \mu$
- Any change in lattice parameters? **No (c-axis, discussion)**
- Hall Effect **(see next slide)**
- X-ray Photoemission Spectroscopy: Input as to where F goes in the lattice?
- DFT calculations: where might the F be going?

# Hall Effect of Fluorinated BaFe<sub>2</sub>As<sub>2</sub>

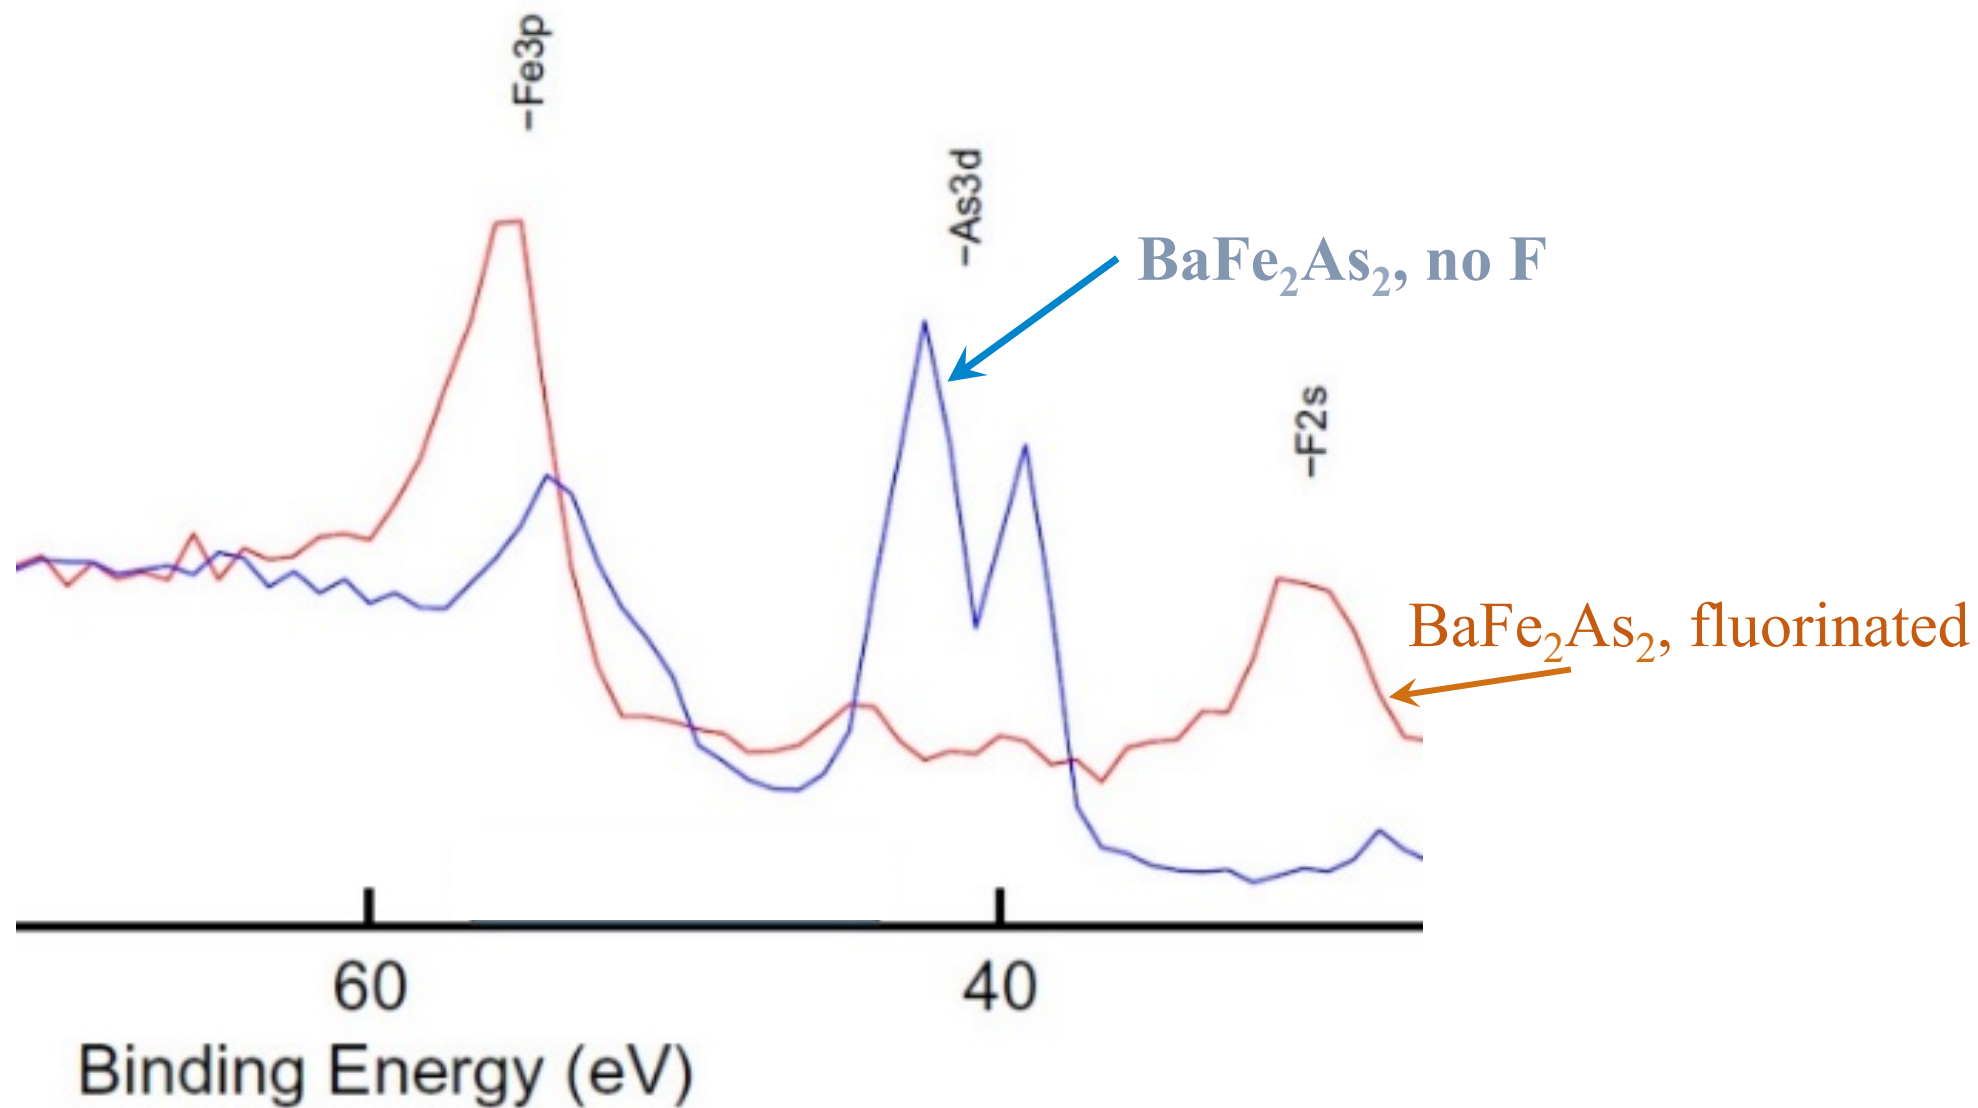

# Focus on Fluorinated $\text{BaFe}_2\text{As}_2$ and Its Properties

-What are the Important Questions?-

- How deep is the superconductivity?  $5 - 10 \mu$
- Any change in lattice parameters? No (discussion)
- Hall Effect *electron concentration decreases with F doping (??)*
- X-ray Photoemission Spectroscopy: Input as to where F goes in the lattice? (see next slide)
- DFT calculations: where might the F be going?

# Photoemission Data on Fluorinated $\text{BaFe}_2\text{As}_2 \Rightarrow$ As is replaced by F

This XPS result matched our thinking at the time

# Focus on Fluorinated $\text{BaFe}_2\text{As}_2$ and Its Properties

-What are the Important Questions?-

- How deep is the superconductivity?  $5 - 10 \mu$  (definitely not 2-d, does not obey Kosterlitz-Thouless)
- Any change in lattice parameters? No (c-axis; discussion)
- Hall Effect *electron concentration decreases with F doping*
- X-ray Photoemission Spectroscopy: Input as to where F goes in the lattice? *Arsenic 3d, 4s lines missing near surface*
- calculations: where might the F be going?

# Interstitial sites for F in t-BaFe<sub>2</sub>As<sub>2</sub>

- Search for possible interstitial sites for F defect
  1. Create 3D mesh over irreducible part of cell with 0.1 Å spacing
  2. Add F atom to cell at coordinates of mesh point
  3. Calculate single point energy of cell using UFF method
  4. Repeat for each mesh point
  5. Sort coordinates with lowest energies
- Found three low-energy interstitial sites

# F impurity calculation results

Impurity site	$\Delta E_{\downarrow raw}$ (eV)	$\Delta E_{\downarrow true}$ (eV)	$V_{\downarrow imp}$ (Å <sup>3</sup> )	$d_{\downarrow ideal}$ (Å)
Ba sub.	-4.28, -1.58	1.98, 6.04	12.6	0.00
Fe sub.	2.96, -1.61	3.30, 6.01	8.6	0.00
As sub.	-2.06, -0.71	4.20, 6.91	-5.9	0.13
2b int.	-4.51	1.76, 3.11	18.8	0.00
4e int.	-2.82	3.44, 4.80	21.6	1.14
8g int.	-4.20	2.06, 3.41	19.8	1.43

## What have we learned; **what are remaining questions?**

- Not 2-d, not Kosterlitz Thouless behavior
- Fluorine gives reproducible (over 200 samples, always the same  $T_c$  with 1 or 2 K) filamentary superconductivity. No diamagnetic shielding
- At least according to XPS, fluorine replaces arsenic in the lattice
- According to calculations, fluorine replacing arsenic is most consistent with the calculated volume of the impurity,  $V_{\text{imp}}$ .

# F impurity calculation results

- At least according to XPS, fluorine replaces arsenic in the lattice
- According to calculations, fluorine replacing arsenic is most consistent with the calculated volume of the impurity,  $V_{imp}$ .
- **Hall effect**
- **According to calculations, As substitution is energetically much less favorable than interstitial placement of the fluorine.**
- **Mechanism for the superconductivity:**
  - $T_{SDW}$  is  $\sim$  unchanged (caveat)
  - Charge doping?
  - Defect mechanism

## Mechanism for Superconductivity – Defects?

- Paglione group (Saha et al. PRL 103, 037005 (2009)) proposed defects as being important in their  $\text{SrFe}_2\text{As}_2$  as-prepared crystal work: “internal crystallographic strain originating from c-axis-oriented planar defects plays a central role in promoting the appearance of superconductivity under ambient pressure conditions in  $\sim 90\%$  of as-grown crystals.”
- Paul Chu’s group (Wei et al., Phil Mag 94, 2562 (2014)) Explanation of  $T_c=49$  K (filamentary but some ( $\leq 3\%$ ) low field ( $H < 1$  G) diamagnetic shielding) in Pr-doped  $\text{CaFe}_2\text{As}_2$ :
  - enhanced  $T_c$  up to 49 K – **doping independent  $T_c$ , rules out  $T_c = f(\text{carrier density})$**
  - may have occurred at the interfaces associated with strains and/or defects

# What have we learned; **what are remaining questions?**

- Not 2-d, not Kosterlitz Thouless behavior
- Fluorine gives reproducible (over 200 samples, always the same  $T_c$  with 1 or 2 K) filamentary superconductivity. No diamagnetic shielding
- At least according to XPS, fluorine replaces arsenic in the lattice

- **Mechanism for the superconductivity:**
  - $T_{SDW}$  is  $\sim$  unchanged (caveat)
  - Charge doping?
  - Defect mechanism
  - . . . . .

Comments, Suggestions?

# Raw and true defect formation energies

- Substitutional raw defect formation energy:

$$\Delta E_{\text{raw}} [F \downarrow X] = E[F \downarrow X] - E[\text{bulk}] + \mu \downarrow X$$

- $E[F \downarrow X]$  - energy of supercell with fluorine at  $X = \text{As, Fe, Ba}$
- $E[\text{bulk}]$  - energy of the perfect supercell (without defect)
- $\mu \downarrow X$  - reference chemical potential for  $X = \text{As, Fe, Ba}$

- Interstitial raw defect formation energy:

$$\Delta E_{\text{raw}} [F \downarrow i] = E[F \downarrow i] - E[\text{bulk}]$$

- $E[F \downarrow i]$  - energy of supercell with fluorine at interstitial site

- True defect formation energy:

$$\Delta E_{\text{true}} = \Delta E_{\text{raw}} - \mu \downarrow F$$

- $\mu \downarrow F$  - reference chemical potential for fluorine

Chemical potentials:

$$\mu \downarrow X [\text{BaFe} \downarrow 2 \text{As} \downarrow 2] \leq \mu \downarrow X \leq \mu \downarrow X [\text{bulk}]$$

$$-4.614 \leq \mu \downarrow \text{Ba} \leq -1.908$$

$$-9.589 \leq \mu \downarrow \text{Fe} \leq -8.237$$

$$-6.022 \leq \mu \downarrow \text{As} \leq -4.669$$

Fluorine reservoir:

$$-\infty \leq \mu \downarrow F \leq \mu \downarrow F [\text{F} \downarrow 2]$$

Using  $\text{BaF}_2$  as a reference:

$$\mu \downarrow F = 1/2 (E[\text{BaF} \downarrow 2] - \mu \downarrow \text{Ba})$$

- The two values for “ $E_{\text{raw}}$ ” for the substitution sites are upper and lower bounds depending on the chemical potential of the atom that will be removed. The lower bound represents the chemical potential for the atom in  $\text{BaFe}_2\text{As}_2$  and the upper bound represents the chemical potential for the atom in its elemental ground state structure. The “ $E_{\text{raw}}$ ” values for the interstitial sites are a single value as the sites are initially empty.
- “ $E_{\text{true}}$ ” are then calculated by subtracting the fluorine chemical potential from “ $E_{\text{raw}}$ ”. The range of fluorine chemical potentials is calculated using the compound  $\text{BaF}_2$  as a reference, which gives an upper or lower bound depending on the chemical potential for Ba.
- “ $V_{\text{imp}}$ ” is the impurity volume and is defined as  $V_{\text{imp}} = V(\text{with F}) - V(\text{bulk})$ , where  $V(\text{with F})$  is the volume of the  $\text{BaFe}_2\text{As}_2$  cell with fluorine at a given site and  $V(\text{bulk})$  is the volume of the bulk  $\text{BaFe}_2\text{As}_2$  cell.
- “ $d_{\text{ideal}}$ ” is the distance the fluorine atom has displace from the ideal site, interstitial or substitutional, after relaxation of the atoms/cell.
