# Recap: The Via Lactea II Subhalo Population

Subhalos have a “cuspy” inner density profile down to our resolution limit...

...and have a steeply rising  $V_{\max}$  function. A single power law down to  $\sim 3$  km/s.

Einasto:  $\ln \frac{\rho(r)}{\rho_s} = -\frac{2}{\alpha} [(r/r_s)^\alpha - 1]$

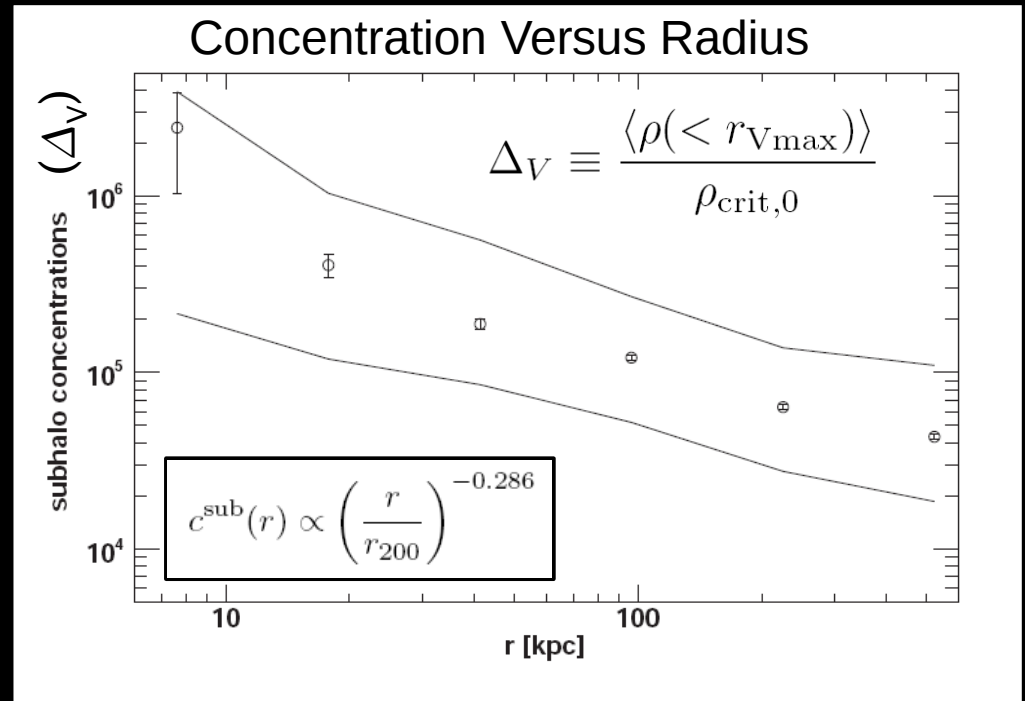

GNFW:  $\rho(r) = \frac{\rho_s}{(r/r_s)^\gamma (r/r_s + 1)^{3-\gamma}}$

$$N(> V_{\max}) = 0.036 \left( \frac{V_{\max}}{V_{\max, \text{host}}} \right)^{-3}$$

# The Subhalo Population – Tidal Mass Loss

- Tidal mass loss is stronger for more massive halos (higher  $V_{\max}$  @  $z=1$ ).
- Halos with  $V_{\max}=10$  km/s retain about 40% of their mass from  $z=1$  to today.
- **97% of all  $z=1$  subhalos still have an identifiable remnant at  $z=0$ .**

- **Subhalos are more concentrated in the inner regions.**
- This due to both tidal stripping and an earlier formation time.
- $c(r=8\text{kpc}) \approx 3 \times c(\text{field})$

# The Subhalo Population – Spatial Distribution

The subhalo radial distribution is **anti-biased** with respect to the DM density: fewer subhalos in the center.

(cf. Ghigna et al. 2000; de Lucia et al. 2004)

## Depends on selection:

- strongest for  $M(z=0)$ -selected,
- weaker for  $V_{\text{max}}(z=0)$ -selected,
- disappears down to  $\sim 30$  kpc for  $\text{peak}(V_{\text{max}})$ -selected.

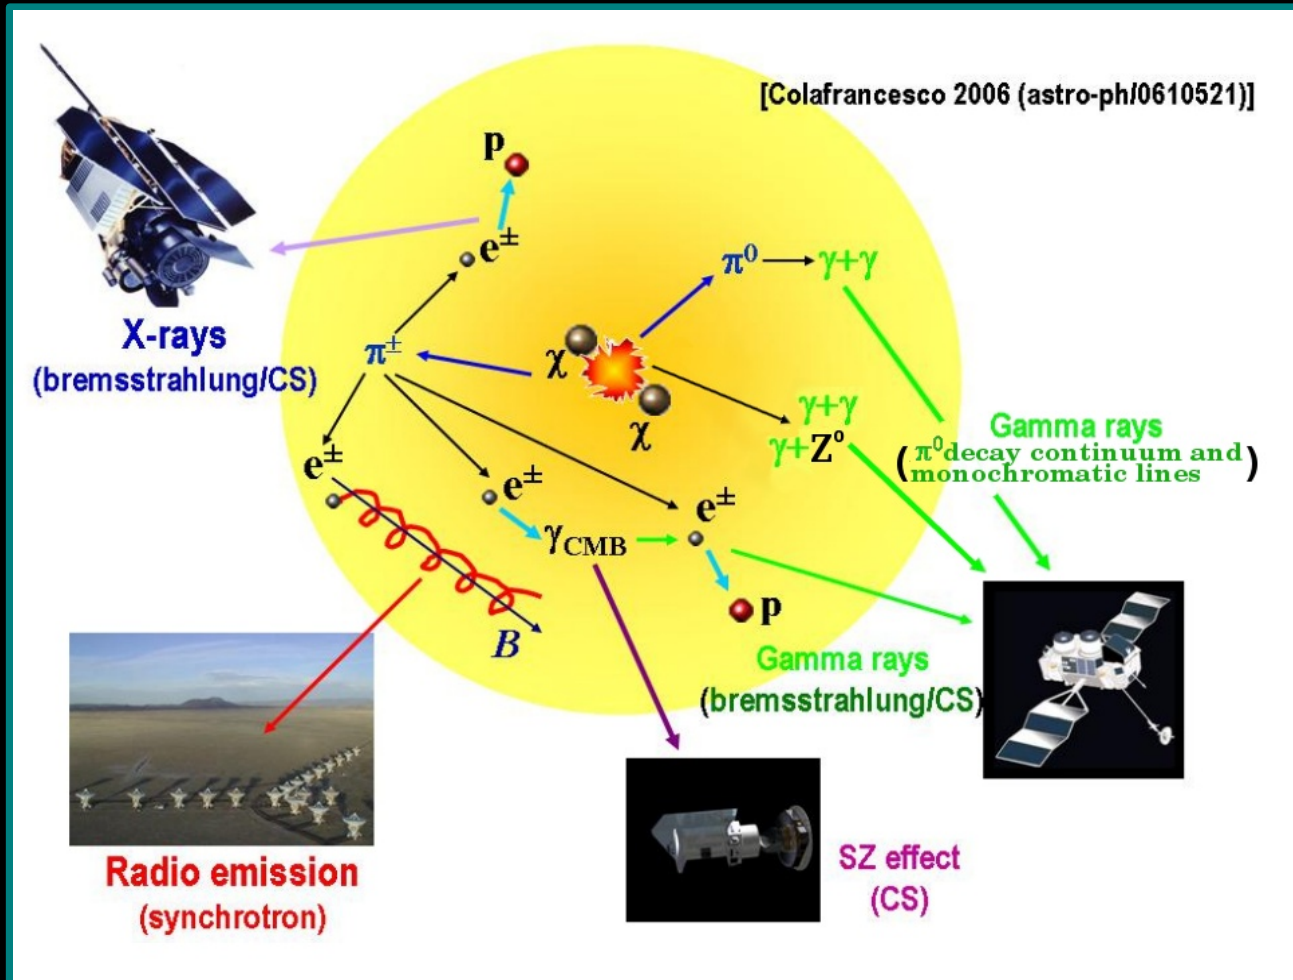

(cf. Nagai & Kravtsov 2005; Faltenbacher & Diemand 2006)

# Gamma rays from WIMP annihilations

## DM (WIMP) annihilation signal

Many different DM candidates:  
axions, WIMPs (neutralino,  
Kaluza-Klein, ...), etc.

In the following: DM = lightest  
SUSY particle (neutralino)

$\gamma$ 's from neutralino annihilation:

- a)  $\chi\chi \rightarrow \gamma\gamma$
- b)  $\chi\chi \rightarrow \gamma Z^0$
- c)  $\chi\chi \rightarrow \{WW, Z^0Z^0, b\bar{b}, t\bar{t}, u\bar{u}\}$

a)+b) spectral line, lower  $\langle\sigma v\rangle$   
c) photon continuum from  $\pi^0$   
decay, higher  $\langle\sigma v\rangle$ ,  
more ambiguous signal

# Gamma rays from WIMP annihilations

Cross section  $\langle\sigma v\rangle$  and particle mass very uncertain!

Colafrancesco et al. (2006)

Many different DM candidates:  
axions, WIMPs (neutralino,  
Kaluza-Klein, ...), etc.

In the following: DM = lightest  
SUSY particle (neutralino)

$\gamma$ 's from neutralino annihilation:

a)  $\chi\chi \rightarrow \gamma\gamma$

b)  $\chi\chi \rightarrow \gamma Z^0$

c)  $\chi\chi \rightarrow \{WW, Z^0 Z^0, b\bar{b}, t\bar{t}, u\bar{u}\}$

a)+b) spectral line, lower  $\langle\sigma v\rangle$

c) photon continuum from  $\pi^0$   
decay, higher  $\langle\sigma v\rangle$ ,  
more ambiguous signal

Quantity	LAT (Minimum Spec.)	EGRET
Energy Range	20 MeV - 300 GeV	20 MeV - 30 GeV
Peak Effective Area <sup>1</sup>	> 8000 cm <sup>2</sup>	1500 cm <sup>2</sup>
Field of View	> 2 sr	0.5 sr
Angular Resolution <sup>2</sup>	< 3.5° (100 MeV) < 0.15° (>10 GeV)	5.8° (100 MeV)
Energy Resolution <sup>3</sup>	< 10%	10%
Deadtime per Event	< 100 μs	100 ms
Source Location Determination <sup>4</sup>	< 0.5'	15'
Point Source Sensitivity <sup>5</sup>	< 6 x 10 <sup>-9</sup> cm <sup>-2</sup> s <sup>-1</sup>	~ 10 <sup>-7</sup> cm <sup>-2</sup> s <sup>-1</sup>

- Launched successfully on June 11th, 2008. Has completed 60 day calibration period. First Light images released.
- Possible local DM annihilation sources:
  - Galactic Center (Berezinsky et al. 1994, Calcaneo-Roldan & Moore 2000, Hooper & Dingus 2004)
  - Dwarf galaxies (Bergstrom & Hooper 2004, Colafrancesco et al. 2007)
  - Nearby subhalo (Bi 2006, Pieri et al. 2005)
  - Coma cluster (Colafrancesco et al. 2006)
- Cosmic Gamma Ray Background (Bergstrom et al. 1999, 2001, Ullio et al. 2002)

Astro physics

Detector properties

$$N_\gamma = \left[ \int_{\text{line of sight}} \rho_{\text{DM}}^2 dl(\psi) \right] \frac{\langle \sigma v \rangle}{2 M_\chi^2} \left[ \int_{E_{th}}^{M_\chi} \left( \frac{dN_\gamma}{dE} \right)_{\text{SUSY}} A_{\text{eff}}(E) dE \right] \frac{\Delta\Omega}{4\pi} \tau_{\text{exp}}$$

Particle physics

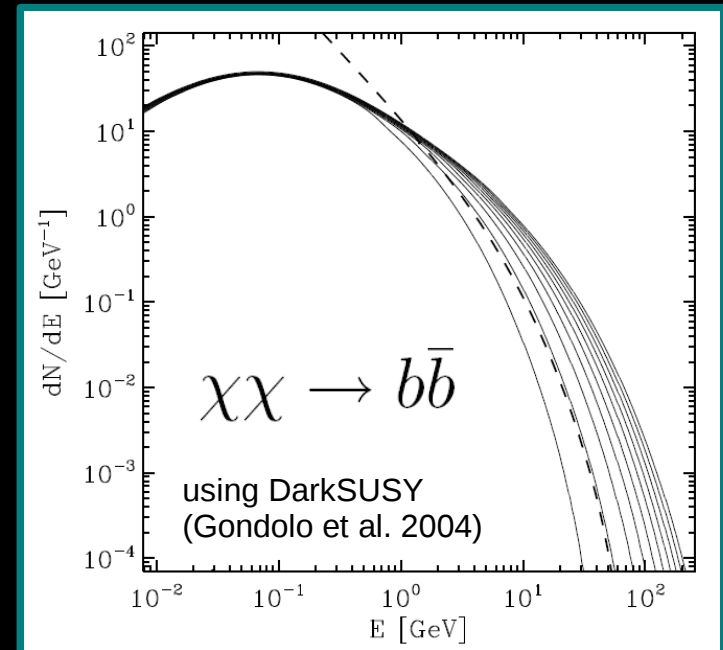

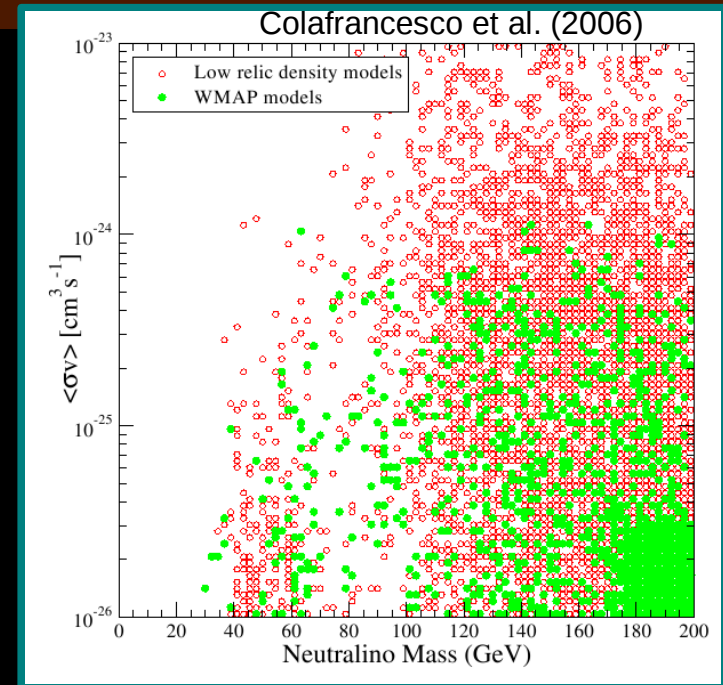

# Simulated Dark Matter Annihilation Map

# Can We Make Quantitative Predictions?

$$N_\gamma = \left[ \int_{\text{line of sight}} \rho_{\text{DM}}^2 dl(\psi) \right] \frac{\langle \sigma v \rangle}{M_\chi^2} \left[ \int_{E_{\text{th}}}^{M_\chi} \left( \frac{dN_\gamma}{dE} \right)_{\text{SUSY}} A_{\text{eff}}(E) dE \right] \frac{\Delta\Omega}{4\pi} \tau_{\text{exp}}$$

- 1) Assume a DM particle: mass and cross section, **consistent with relic abundance** ( $\Omega_m$  from WMAP).

# Can We Make Quantitative Predictions?

$$N_\gamma = \left[ \int_{\text{line of sight}} \rho_{\text{DM}}^2 dl(\psi) \right] \frac{\langle \sigma v \rangle}{M_\chi^2} \left[ \int_{E_{th}}^{M_\chi} \left( \frac{dN_\gamma}{dE} \right)_{\text{SUSY}} A_{\text{eff}}(E) dE \right] \frac{\Delta\Omega}{4\pi} \tau_{\text{exp}}$$

- 1) Assume a DM particle: mass and cross section, **consistent with relic abundance** ( $\Omega_m$  from WMAP).
- 2) Use expected Fermi/LAT **detector sensitivity**:
  - $A_{\text{eff}}(E)$
  - angular resolution ( $\sim 9$  arcmin)
  - effective exposure time ( $\sim 2$  years)

# Can We Make Quantitative Predictions?

$$N_\gamma = \left[ \int_{\text{line of sight}} \rho_{\text{DM}}^2 dl(\psi) \right] \frac{\langle \sigma v \rangle}{M_\chi^2} \left[ \int_{E_{th}}^{M_\chi} \left( \frac{dN_\gamma}{dE} \right)_{\text{SUSY}} A_{\text{eff}}(E) dE \right] \frac{\Delta\Omega}{4\pi} \tau_{\text{exp}}$$

- 1) Assume a DM particle: mass and cross section, **consistent with relic abundance** ( $\Omega_m$  from WMAP).
- 2) Use expected Fermi/LAT **detector sensitivity**:
  - $A_{\text{eff}}(E)$
  - angular resolution ( $\sim 9$  arcmin)
  - effective exposure time ( $\sim 2$  years)
- 3) Consider both astrophysical and DM annihilation **backgrounds**.

# Backgrounds: Extragalactic GR Background

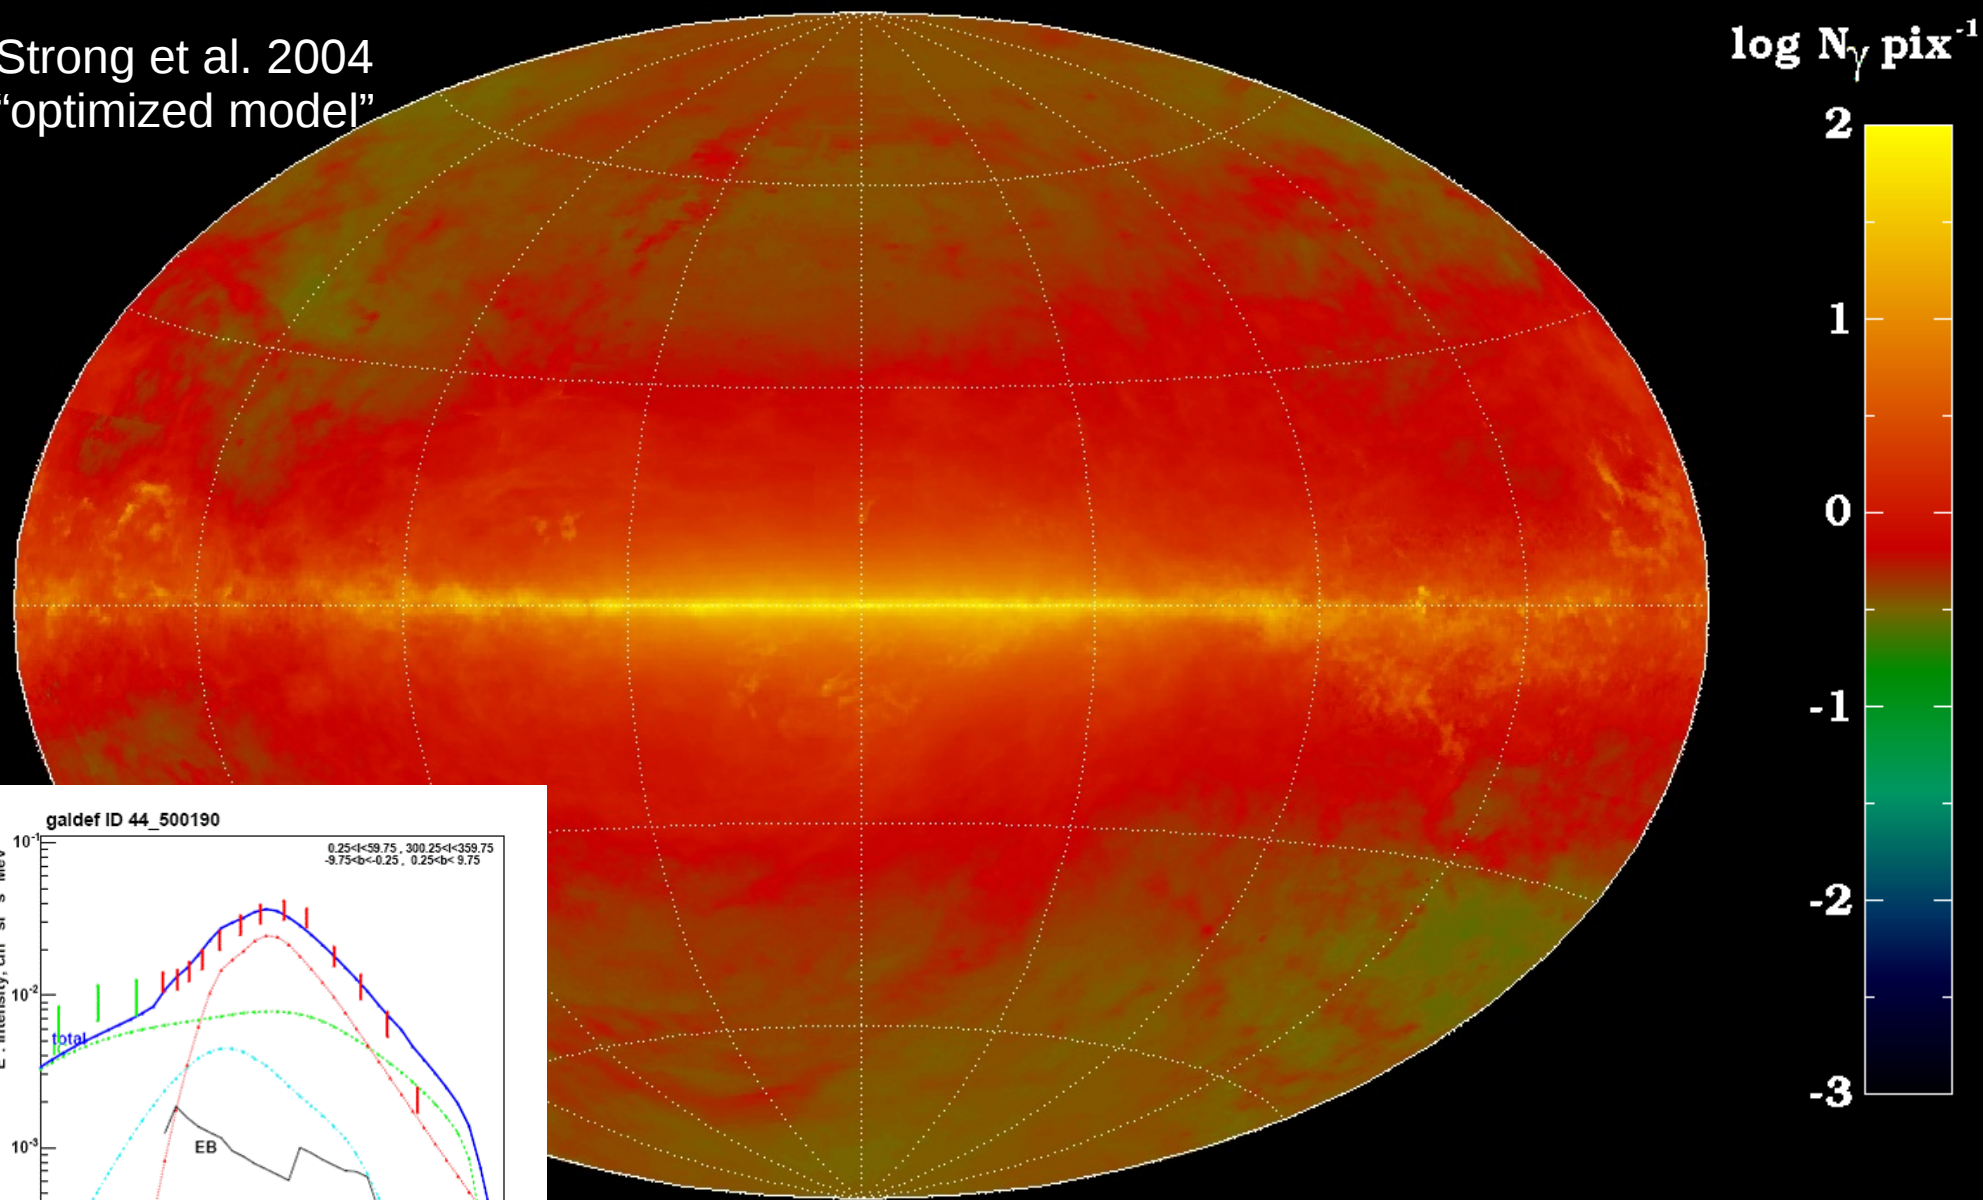

$$\frac{dN}{dE dA dt d\Omega} = 1.32 \times 10^{-6} \left( \frac{E}{1\text{GeV}} \right)^{-2.1} \text{ GeV}^{-1} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$$

From EGRET: Sreekumar et al. 1998 and Baltz et al. 1999

Kuhlen, Diemand, & Madau (2008)

## Substructure in the dark halo

- annihilation radiation from WIMP dark matter may be observable by *GLAST/Fermi*

Kuhlen et al. (2008)

Kuhlen

- strongest signal from the sub-halos
- detectable sub-halos resolved by Fermi
- most prominent sub-halo typically has  $d \sim 20\text{-}40$  kpc and  $M \sim 10^7\text{-}10^9 M_\odot$

Springel et al. (2008)

Frenk

- strongest signal from the smooth main halo
- detectable sub-halos unresolved by Fermi
- most prominent sub-halo typically has  $d \sim 3\text{-}30$  kpc and  $M \sim 10^6\text{-}10^7 M_\odot$

# Substructure in the dark halo

- most prominent sub-halo typically has  $d \sim 3\text{-}30$  kpc and  $M \sim 10^6\text{-}10^7 M_\odot$

# Indirect Detection: Conclusions

- Indirect detection is a promising way to **test a central prediction of  $\Lambda$ CDM**: abundant small scale structure.
- The observability of such a **signal is very uncertain** and depends on the nature, mass, and cross section of the dark matter particle.
- For reasonable values of the DM particle physics parameters ( $M_\chi=50-500$  GeV,  $\langle\sigma v\rangle=1-10\times 10^{-26}$  cm<sup>3</sup> s<sup>-1</sup>) **GLAST/Fermi may detect a handful of subhalos**.
- Detectable subhalos have  $V_{\max}$  ranging from  $>\sim 20$  km/s down to  $\sim 5$  km/s.
- Most **detectable subhalos would be resolved**, are more likely to be found away from the Galactic center, and have **typical distances of 20-30 kpc**.
