

Recent Results from IceCube

Searches for high-energy neutrinos and future plans

Cosmic Rays

Where (and how) are they accelerated?

- ▶ Charged particles with energies up to 10^{21} eV (ZeV) (!)
- ▶ Their sources (especially at the highest energies) are still mostly unknown

TeV Neutrinos

Observing astrophysical neutrinos allows conclusions about the acceleration mechanism of Cosmic Rays

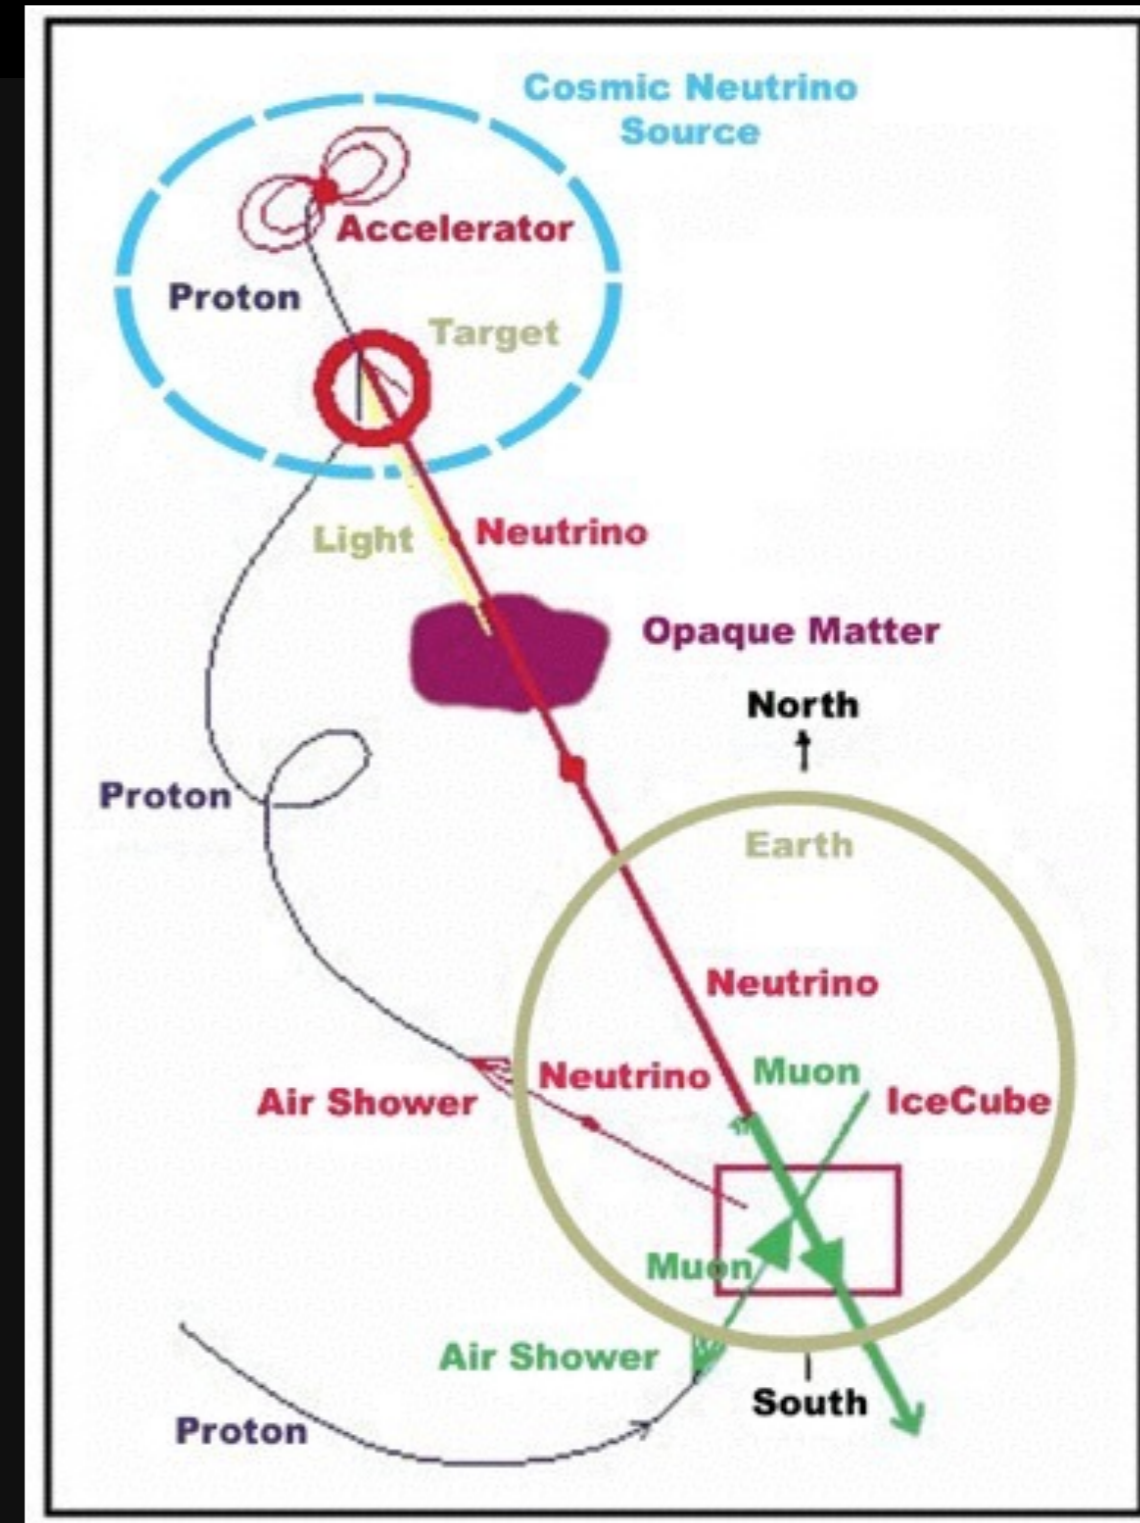

▶ Neutrinos from cosmic ray interactions in:

- Atmosphere
- Cosmic Microwave Background
- Gamma Ray Bursts (Acceleration Sites)
- Active Galactic Nuclei (Acceleration Sites)
- ?

Why Neutrinos?

Neutrinos are ideal astrophysical messengers

- ▶ Travel in straight lines
- ▶ Very difficult to absorb in flight

Interesting Neutrinos above 1 TeV

▶ Atmospheric neutrinos (π/K)

- dominant < 100 TeV

▶ Atmospheric neutrinos (charm)

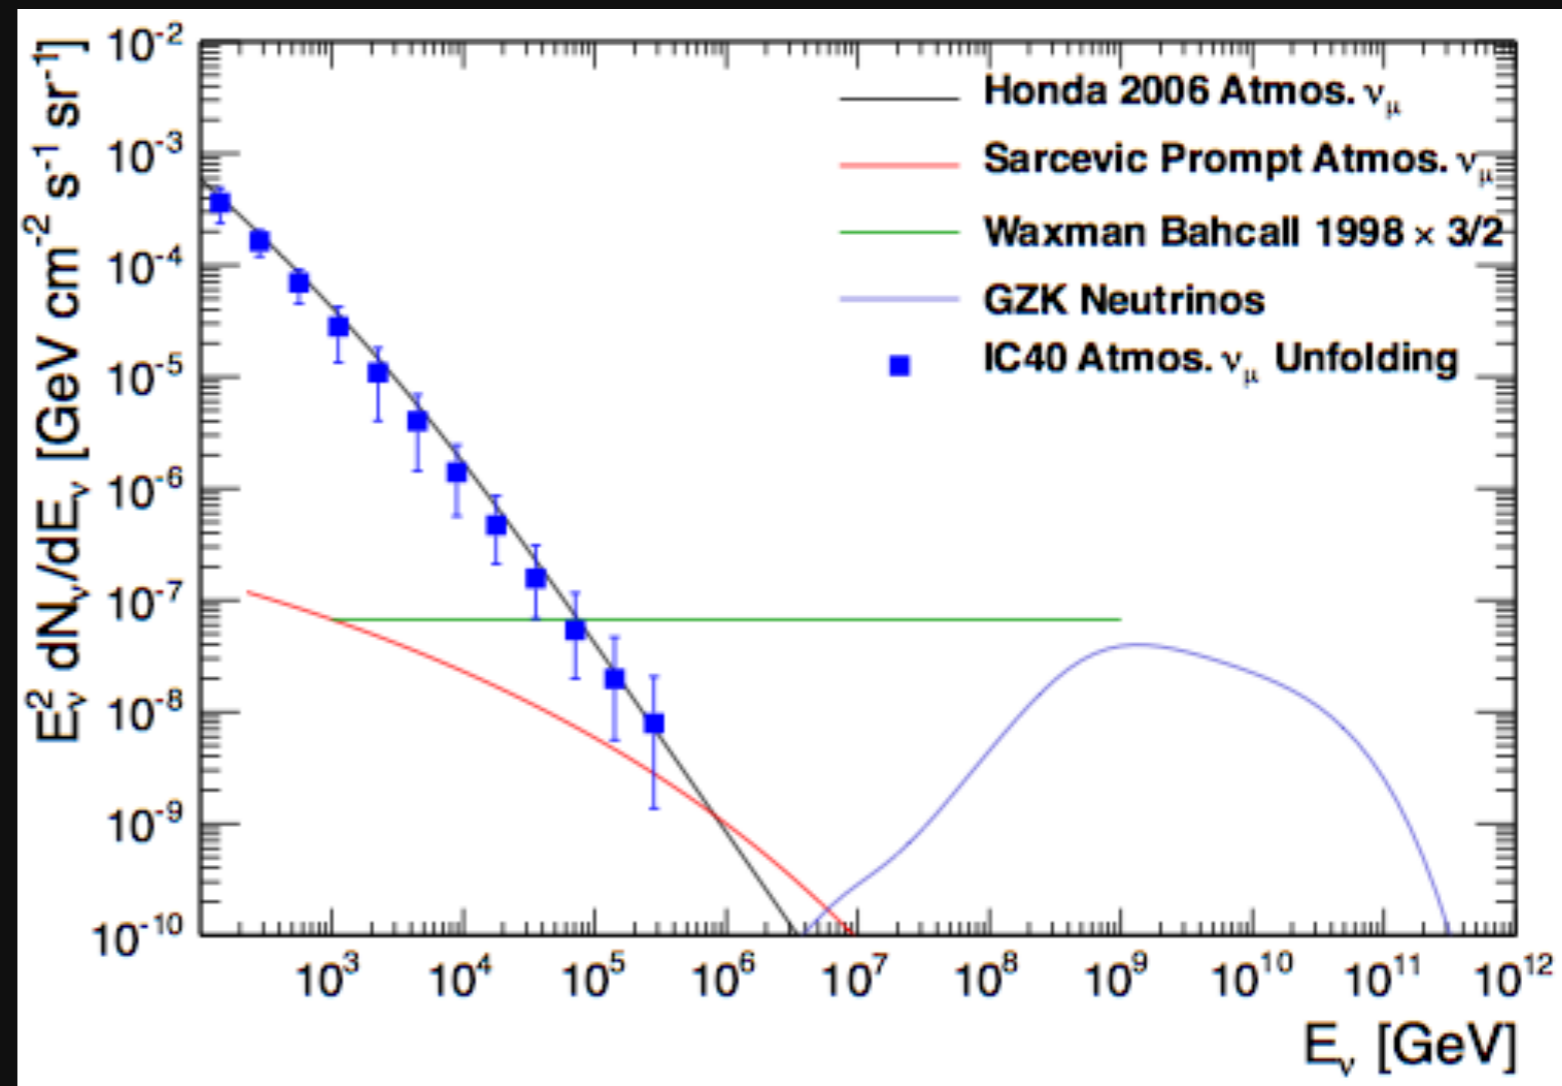

- “prompt” ~ 100 TeV

▶ Astrophysical neutrinos

- maybe dominant > 100 TeV

▶ Cosmogenic neutrinos

- $> 10^6$ TeV

The IceCube Neutrino Observatory

Deployed in the deep glacial ice at the South Pole

- ▶ **5160 PMTs**
- ▶ **1 km³ volume**
- ▶ **86 strings**
- ▶ **17 m vertical spacing between PMTs**
- ▶ **125 m string spacing**
- ▶ **Completed 2010**

The IceCube Neutrino Observatory

Neutrinos are detected by looking for Cherenkov radiation from secondary particles (muons, particle showers)

The IceCube Neutrino Observatory

Neutrinos are detected by looking for Cherenkov radiation from secondary particles (muons, particle showers)

time delay

Neutrino Event Signatures

Signatures of signal events

CC Muon Neutrino

track (data)

factor of ≈ 2 energy resolution
< 1° angular resolution at high energies

Neutral Current / Electron Neutrino

cascade (data)

$\approx \pm 15\%$ deposited energy resolution
 $\approx 10^{\circ}$ angular resolution
(at energies $\gtrsim 100$ TeV)

CC Tau Neutrino

“double-bang” ($\gtrsim 10$ PeV) and other signatures (simulation)

(not observed yet)

Backgrounds and Systematics

► Backgrounds:

- Cosmic Ray Muons
- Atmospheric Neutrinos

► Largest Uncertainties:

- Optical Properties of Ice
- Energy Scale Calibration
- Neutral current / ν_e degeneracy

A bundle of muons from a CR interaction in the atmosphere (also observed in the “IceTop” surface array)

Calibration

Various calibration devices/methods to control detector systematics

- ▶ **LED flashers on each DOM**
- ▶ **In-ice calibration laser**
- ▶ **Cosmic ray energy spectrum**
- ▶ **Moon shadow**
- ▶ **Atmospheric Neutrino Energy Spectrum**
- ▶ **Minimum-ionizing muons**

**Moon Shadow in Cosmic Rays
Muons in IceCube (59 strings)**

Studying Neutrinos

Many possible analyses!

▶ **High-energy:**

- Point-source searches looking for clustering in the sky
- Diffuse fluxes above the atmospheric neutrino background
- Gamma-ray bursts searches (models excluded by IceCube: Nature 484 (2012))
- Ultra-high energy “GZK” neutrinos from proton interactions on the CMB

▶ **Low energy:**

- Neutrino oscillations + more with PINGU upgrade!

▶ **Others:**

- Dark Matter / WIMPs
- ...

The (Very) High-Energy Tail

Searching for a signal above the atmospheric neutrino background

Signals and Backgrounds

Signal

- ▶ Dominated by showers ($\sim 80\%$ per volume) from oscillations
- ▶ High energy (benchmark spectrum is typically E^{-2})
- ▶ Mostly in the Southern Sky due to absorption of high-energy neutrinos in the Earth

Background

- ▶ Track-like events from Cosmic Ray muons and atmospheric ν_{μ}
- ▶ Soft spectrum ($E^{-3.7} - E^{-2.7}$)
- ▶ Muons in the Southern Sky, neutrinos from the North

Results

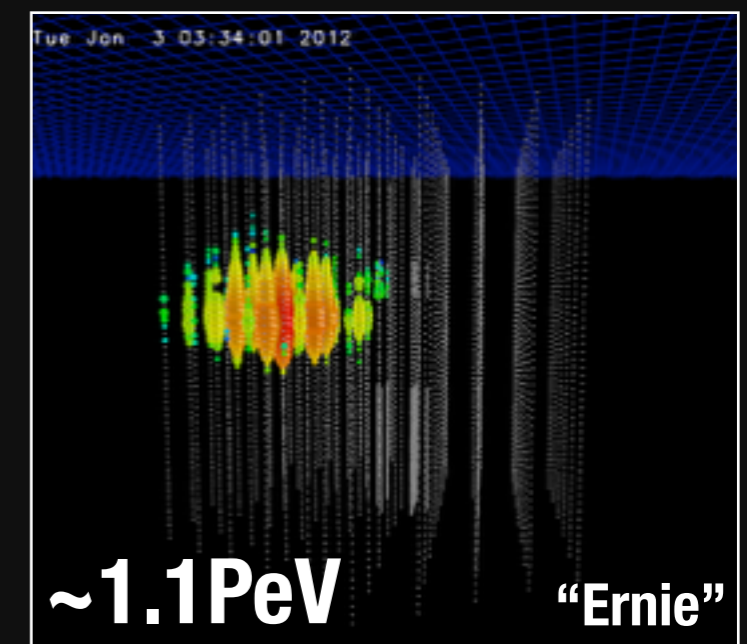

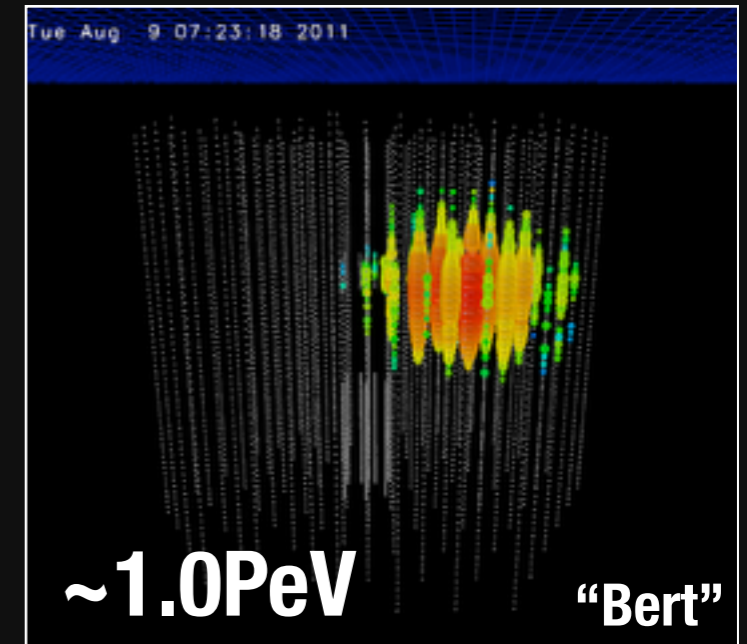

Appearance of ~ 1 PeV cascades as an at-threshold background

▶ Two very interesting events in IceCube (between May 2010 and May 2012)

- shown at Neutrino '12
- 2.8σ excess over expected background in GZK analysis
- (PRL 111, 021103 (2013))

▶ There should be more

- GZK analysis is only sensitive to very specific event topologies at these energies

Directional Resolution for Showers

Showers directions reconstructed from timing profile

Directional Resolution for Showers

Another Shower

Directional Resolution for Showers

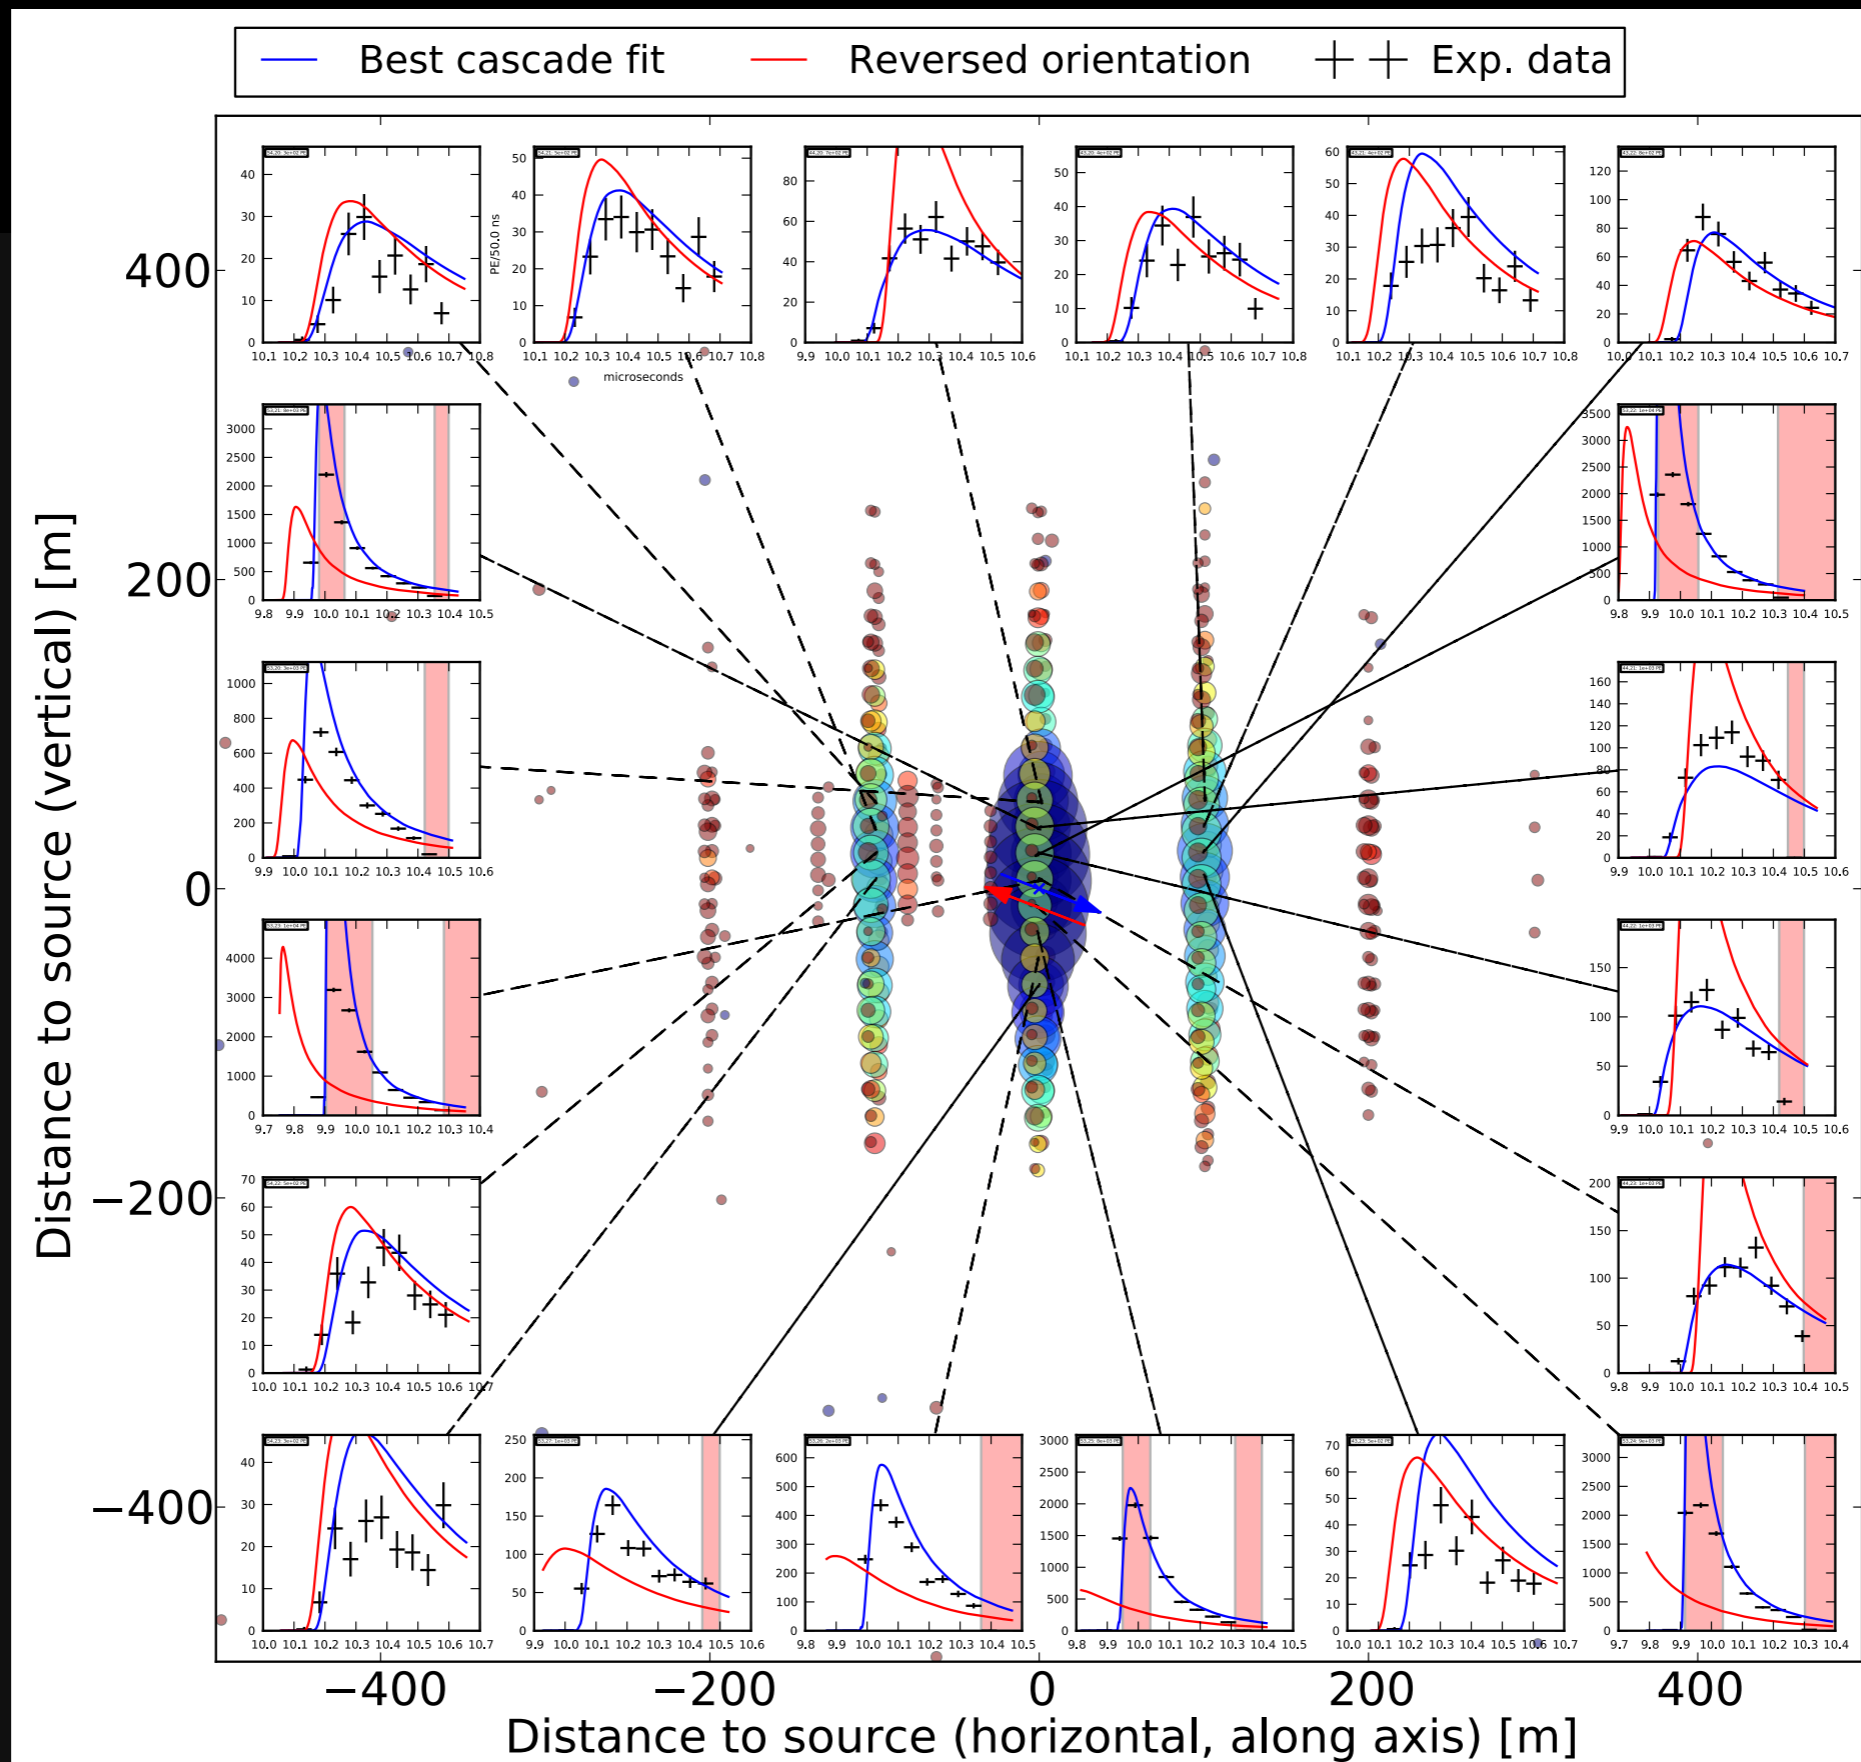

This is how it would look in sea water (just for fun..)

What are they?

Studying individual events in IceCube

What are they?

Energy Reconstruction of EM showers

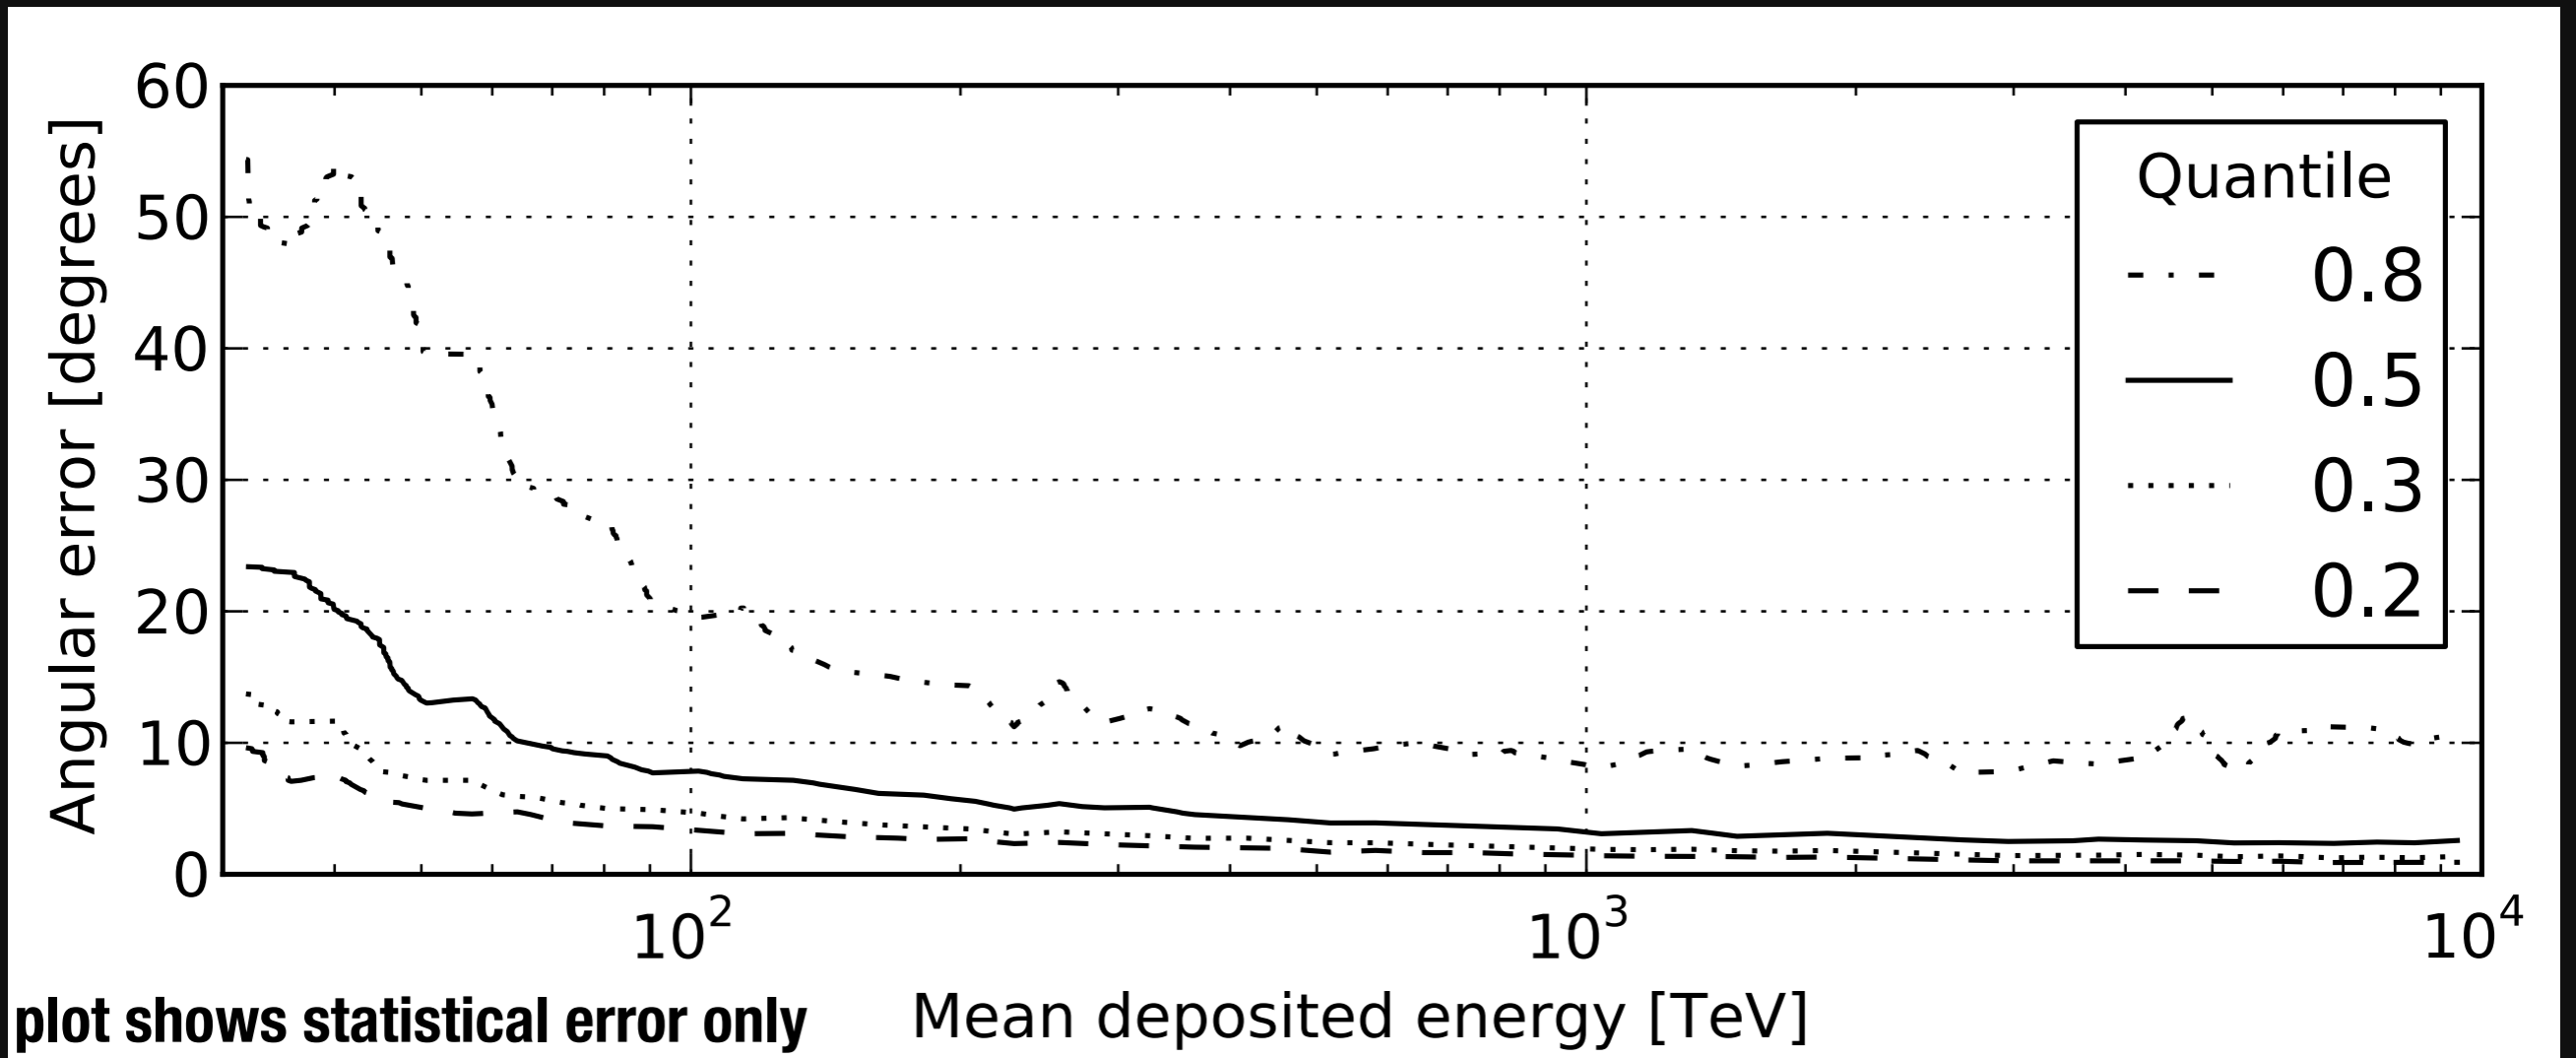

for analysis selection

plot shows statistical error only

Directional Resolution for Showers

Statistical uncertainties in angular reconstruction for showers is small. Dominated by ice systematics!

Directional Resolution for Showers

► **Angular error distributions on the order of 10° - 15° depending on the ice model assumption**

- two ice examples are shown
- aggregate resolution in black

resolution for an individual example event from re-simulation

Things We Know

- ▶ **At least two PeV neutrinos in a 2-year dataset**
- ▶ **Events are downgoing**
- ▶ **Seems not to be GZK (too low in energy)**
- ▶ **Higher than expected for atmospheric background**
- ▶ **Spectrum seems not to extend to much higher energies**
 - (in tension with unbroken E^{-2})

Things We Wanted to Learn

- ▶ **Isolated events or tail of spectrum?**
- ▶ **Spectral slope/cutoff**
- ▶ **Flavor composition**
- ▶ **Where do they come from?**
- ▶ **Astrophysical or air shower physics (e.g. charm)?**
- ▶ **Need more statistics to answer all of these!**

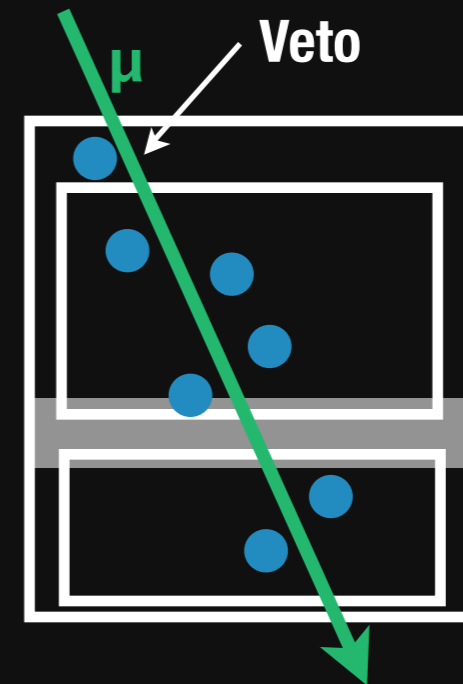

High-Energy Contained Vertex Search

How we found more...

Follow-up Analysis

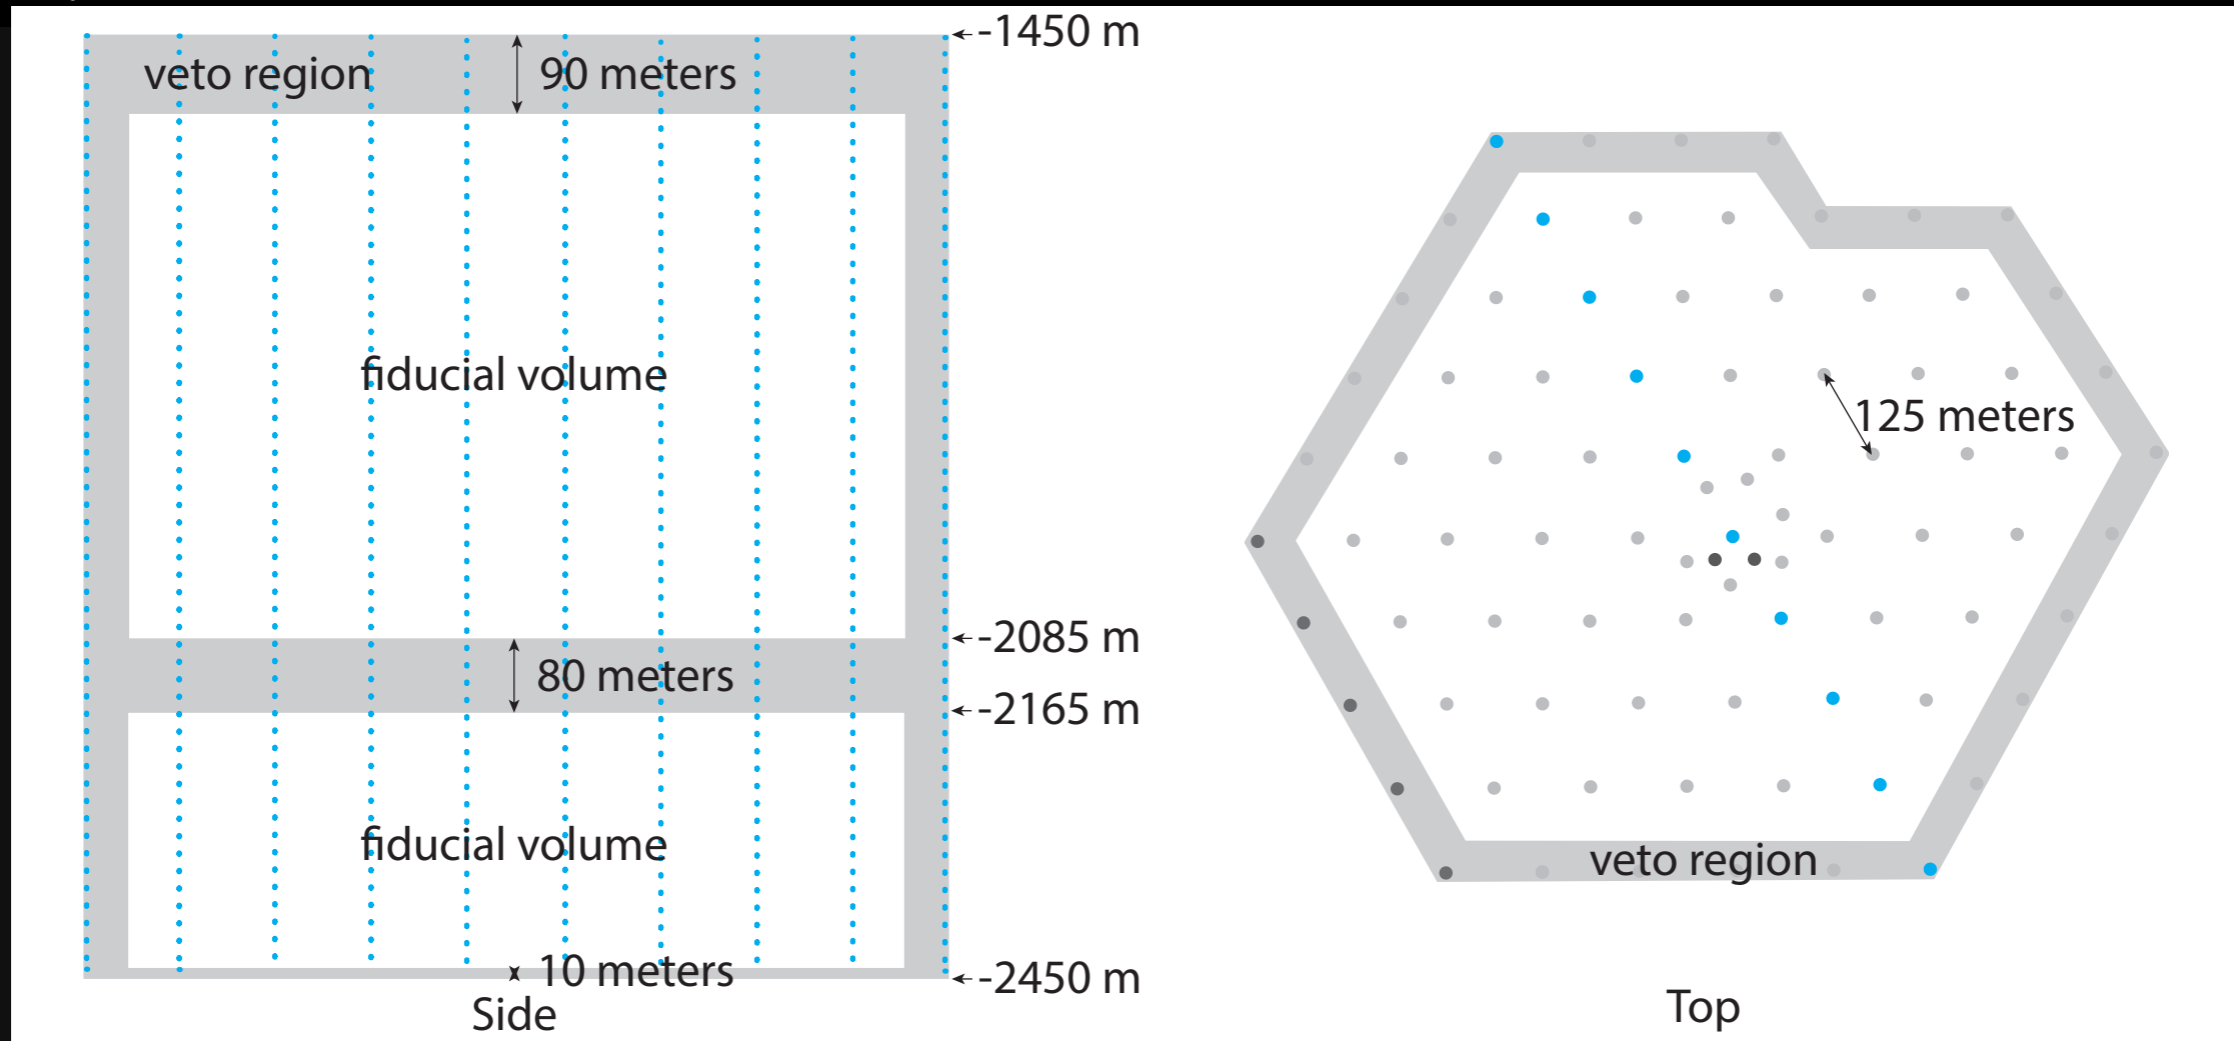

Specifically designed to find these contained events.

- ▶ **Explicit contained search at high energies (cut: $Q_{\text{tot}} > 6000$ p.e.)**
- ▶ **400 Mton effective fiducial mass**
- ▶ **Use atmospheric muon veto**
- ▶ **Sensitive to all flavors in region above 60TeV deposited energy**
- ▶ **Three times as sensitive at 1 PeV**
- ▶ **Estimate background from data**

Background 1 - Atmospheric Muons

Mostly incoming atmospheric muons sneaking in through the main dust layer

- ▶ **Reject incoming muons when “early charge” in veto region**
- ▶ **Control sample available: tag muons with part of the detector - known bkg.**
- ▶ **6 ± 3.4 muons per 2 years (662 days)**

Background 2 - Atmospheric Neutrinos

Very low at PeV energies

- ▶ **Typically separated by energy**
- ▶ **Very low at PeV energies (order of 0.1 events/year)**
- ▶ **Large uncertainties in spectrum at high energies**
- ▶ **$4.6^{+3.7}_{-1.2}$ events in two years (662 days)**
- ▶ **Rate accounts for events vetoed by accompanying muon from the same air shower in the Southern Sky**
- ▶ **Baseline model (prompt neutrinos): Enberg et al. (updated with cosmic-ray Knee model)**

Vetoing Atmospheric Neutrinos

- ▶ Atmospheric neutrinos are made in air showers
- ▶ For downgoing neutrinos, the muons will likely not have ranged out at IceCube
- ▶ High-energy downgoing events that start in the detector are extremely unlikely to be atmospheric

Schönert et al.,
arXiv:0812.4308

- Note: optimal use requires *minimal* overburden to have the highest possible rate of cosmic ray muons!

Effective Volume / Target Mass

Fully efficient above 100 TeV for CC electron neutrinos

About 400 Mton effective target mass

What Did We Find?

26 more events!

What Did We Find?

37 events in 3 years of IceCube data
(988 days between 2010–2013)

- ▶ **36(+1) events observed!**
- ▶ **Estimated background:**
 - ▶ $6.6^{+5.9}_{-1.6}$ atm. neutrinos
 - ▶ 8.4 ± 4.2 atm. muons
- ▶ **One of them is an obvious (but expected) background**
 - ▶ coincident muons from two CR air showers
- ▶ **Gaps like the one between 400TeV and 1PeV appear in 43% of re-simulations from best-fit of continuous power-law**

combining with 2.8σ from GZK result:
 4.8σ for 35+2 events
full likelihood fit of all components:
 5.7σ for 36(+1) events

What Did We Find?

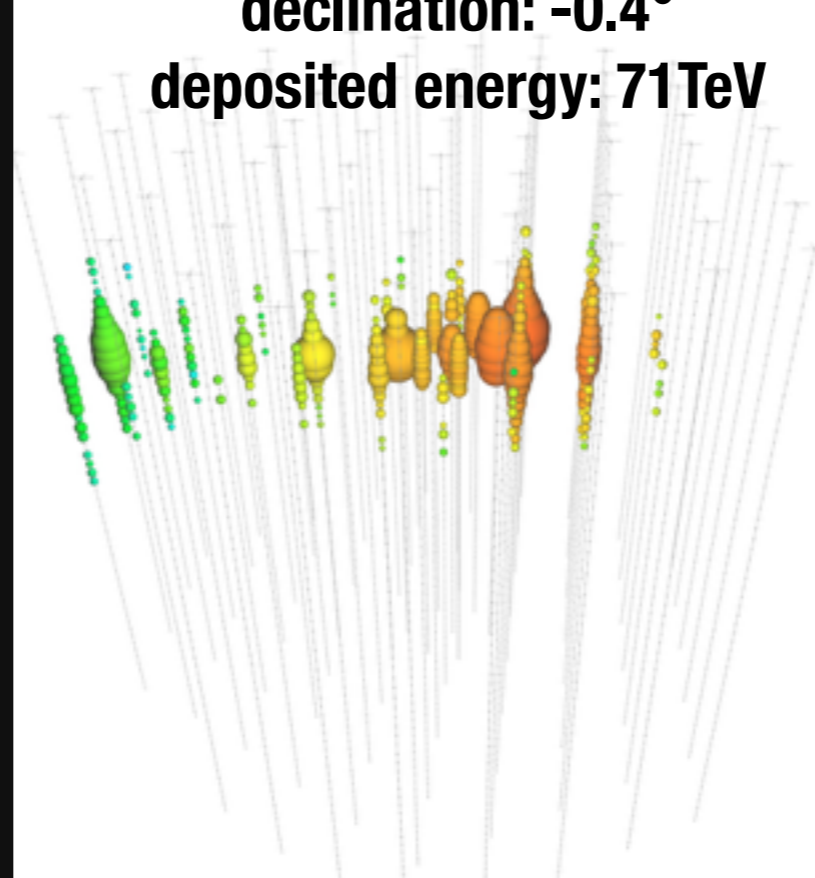

Some examples

declination: -13.2°
deposited energy: 82TeV

declination: -0.4°
deposited energy: 71TeV

declination: 40.3°
deposited energy: 253TeV

Charge Distribution

- ▶ Fits well to tagged background estimate from atmospheric muon data (red) below charge threshold ($Q_{\text{tot}} > 6000$)
- ▶ Hatched region includes uncertainties from conventional and charm atmospheric neutrino flux (blue)

Energy Spectrum

Compatible with benchmark E^{-2} astrophysical model

- ▶ **Harder than any expected atmospheric background**
- ▶ **Merges well into background at low energies**
- ▶ **Potential cutoff at about 2-5 PeV (or softer spectrum)**
- ▶ **Best fit assuming E^{-2} (per-flavor flux):**
 - $0.95 \pm 0.3 \cdot 10^{-8} E^{-2} \text{ GeV cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$
- ▶ **Best fit spectral index: $E^{-2.3}$**

Unfolding to Neutrino Energy

An attempt to plot the spectrum: unfolded to true neutrino energy, simultaneously fitting for backgrounds

assumption: 1:1:1 flavor ratio, 1:1 neutrino:anti-neutrino

Declination Distribution

Or: “zenith distribution” because we are at the South Pole

- ▶ **Compatible with isotropic flux**
- ▶ **Events absorbed in Earth from Northern Hemisphere**
- ▶ **Minor excess in south compared to isotropic, but not significant**

Declination Distribution

Or: “zenith distribution” because we are at the South Pole

- ▶ **Compatible with isotropic flux**

Skymap / Clustering

No significant clustering observed (three years)

(all p-values are post-trial)

Skymap / Clustering

No significant clustering observed (three years)

(all p-values are post-trial)

Skymap / Clustering

No significant clustering observed

- ▶ **Analyzed with a variant of the standard PS method (w/o energy) (i.e. scrambling in RA)**
- ▶ **Most significant excess close to (but not at!) the Galactic Center**
- ▶ **Significance: 7% (not significant)**
- ▶ **Other searches (multi-cluster, galactic plane, time clustering, GRB correlations) not significant either**

Improved Veto Techniques

(arXiv:1410.1749)

- ▶ **What happens to the astrophysical flux below 60 TeV?**
- ▶ **How large is the neutrino flux from atmospheric charm?**
- ▶ **-> Need to observe lower-energy neutrinos, especially from the southern sky.**

Improved Veto Techniques

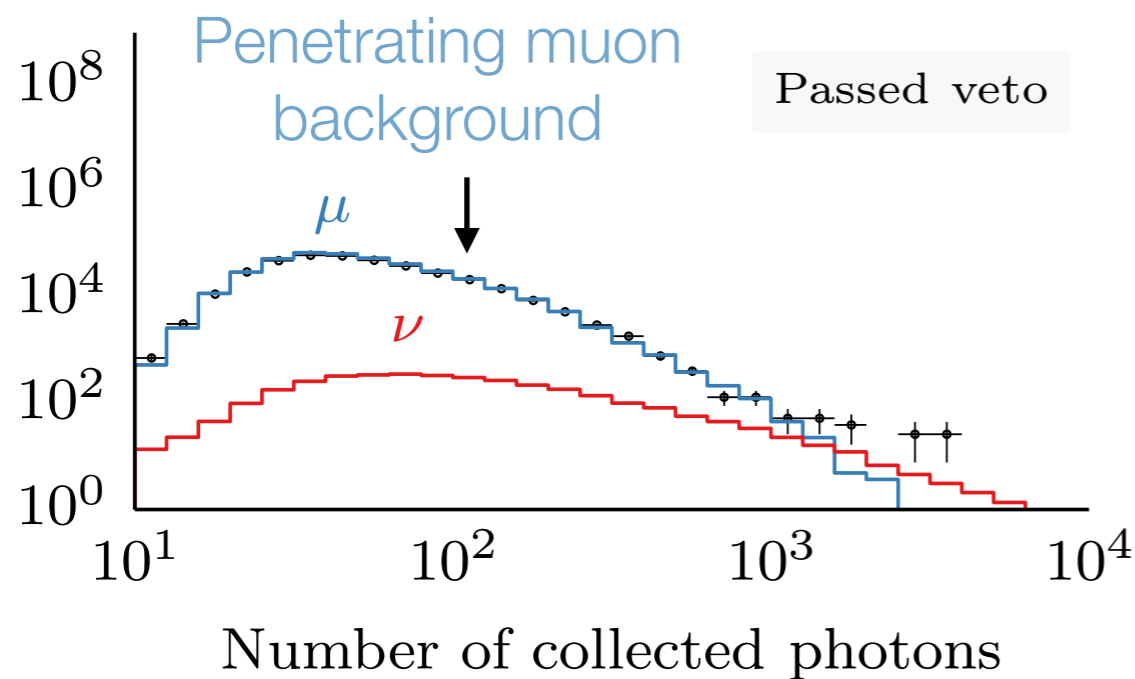

What happens to the astrophysical flux below 60 TeV?

Outer-layer veto

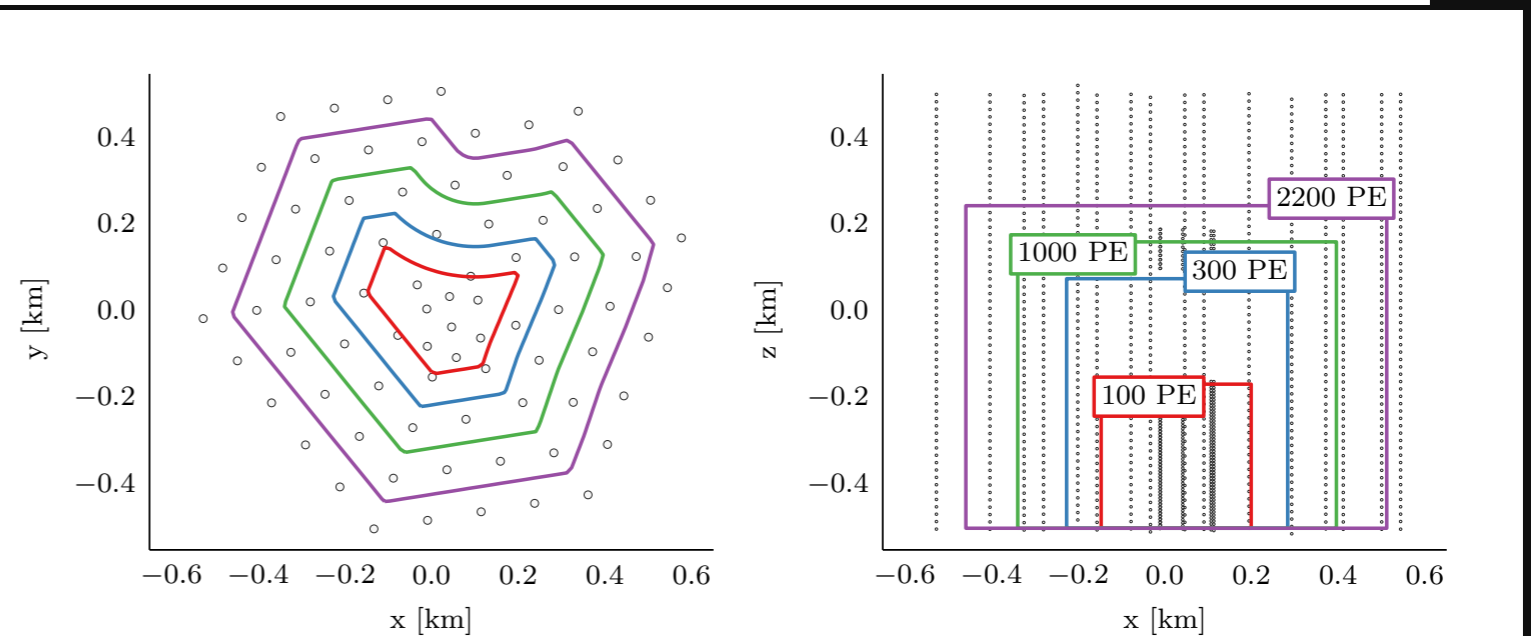

Energy-dependent veto

Neutrino-dominated for $E_{\text{dep}} > 60 \text{ TeV}$

Neutrino-dominated for $E_{\text{dep}} > 1 \text{ TeV}$

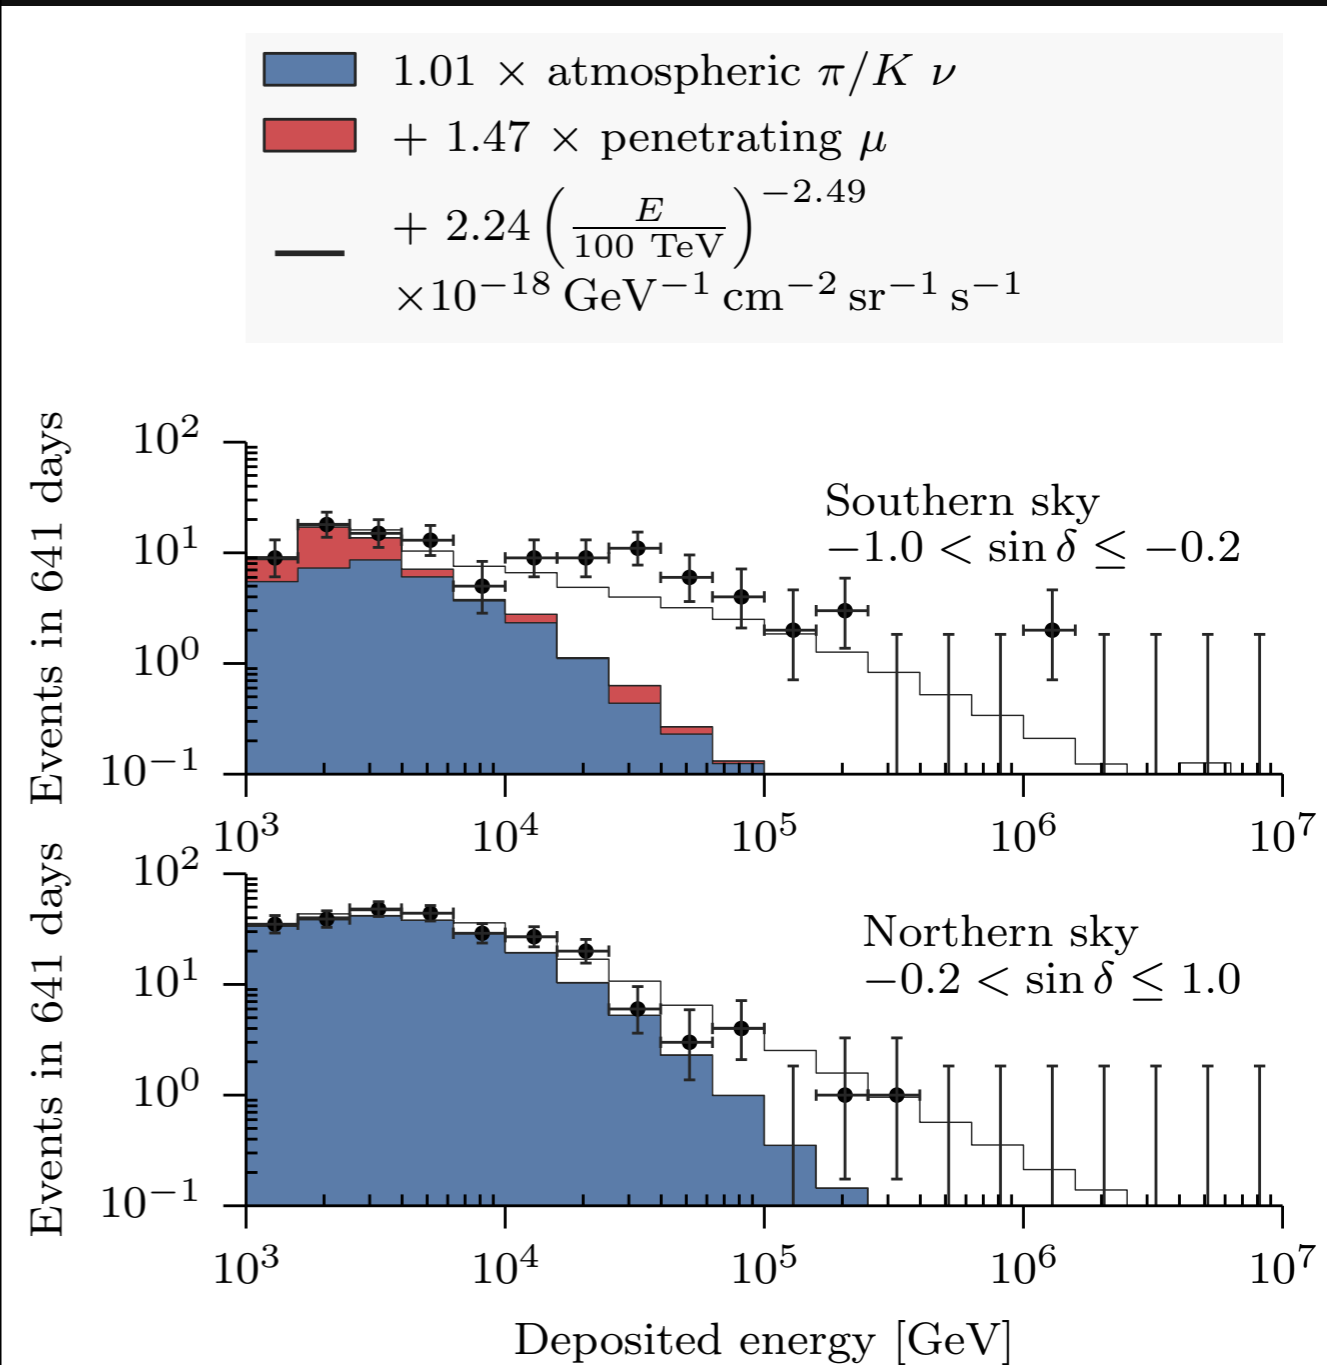

Thicker veto at low energies suppresses penetrating muons without sacrificing high-energy neutrino acceptance

Results

283 cascade and 105 track events in 2 years of data

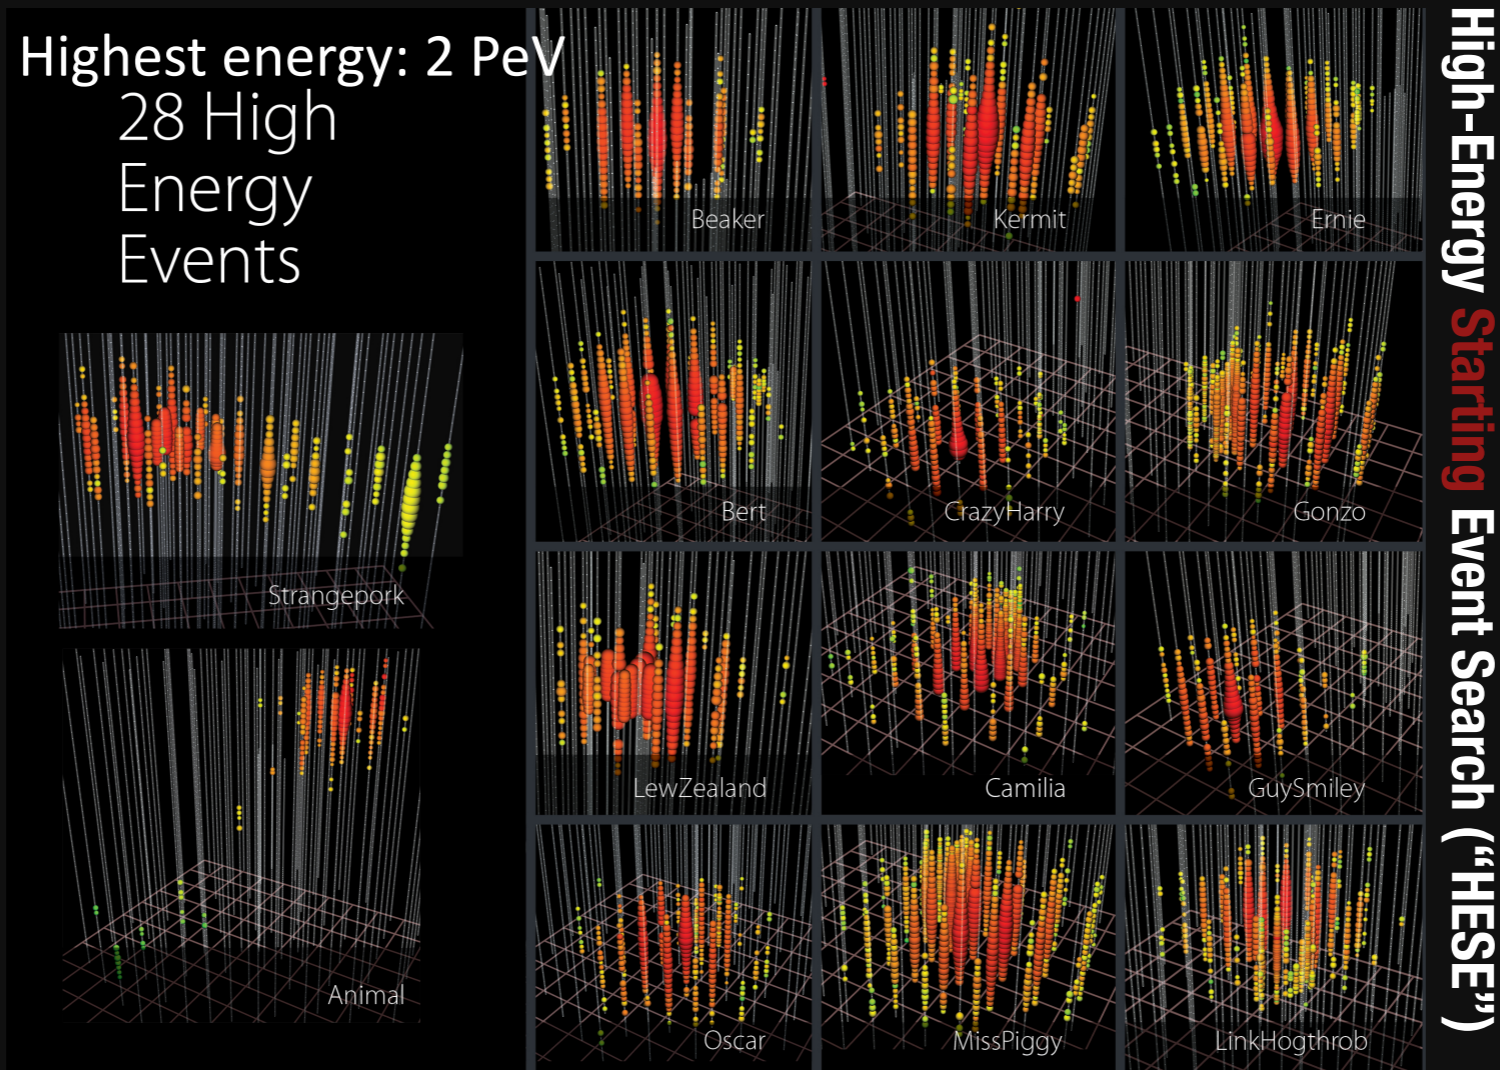

- ▶ **106 > 10 TeV, 9 > 100 TeV (7 of those already in high-energy starting event sample)**
- ▶ **Conventional atmospheric neutrino flux observed at expected level with starting events**
- ▶ **Astrophysical excess continues down to 10 TeV in the southern sky**
- ▶ **Deviation from model at 30 TeV (statistical fluctuation)**
- ▶ **Model-dependent upper limit on flux from charmed meson decay: 1.4 x ERS prediction**

Other Channels?

Most of the “starting” sample consists of showers, with a high acceptance in the southern sky

- ▶ **Deposited (i.e. measured) energies closely related to neutrino energies**
- ▶ **Great for discovering a signal**

Other Channels?

We have now seen a similar flux in the muon channel - at 3.7σ

- ▶ **Similar flux in more “traditional” muon channel, accepting incoming muons, looking below the horizon (northern sky)**

Upgoing Muons - Spectral Components

Two years of data - for E^{-2} spectral assumption - best fit is $E^{-2.2}$
Normalization for E^{-2} : $0.98^{+0.4}_{-0.3} 10^{-8} E^{-2} \text{ GeV cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$

The Future

Extending the sensitivity to higher energies

The Future

At the highest energies: “neutrino = extraterrestrial source”

- ▶ **Lots of cascades, only a few tracks**
 - ▶ cascades are limited by angular resolution $O(10\text{deg})$, dominated by ice systematics
 - ▶ great for measuring a diffuse flux, not so great for astronomy
- ▶ **We need more tracks!**
 - ▶ (and of course we need to continue improving our systematics on the ice for cascades)

Note

For pointing searches we can tolerate more background!

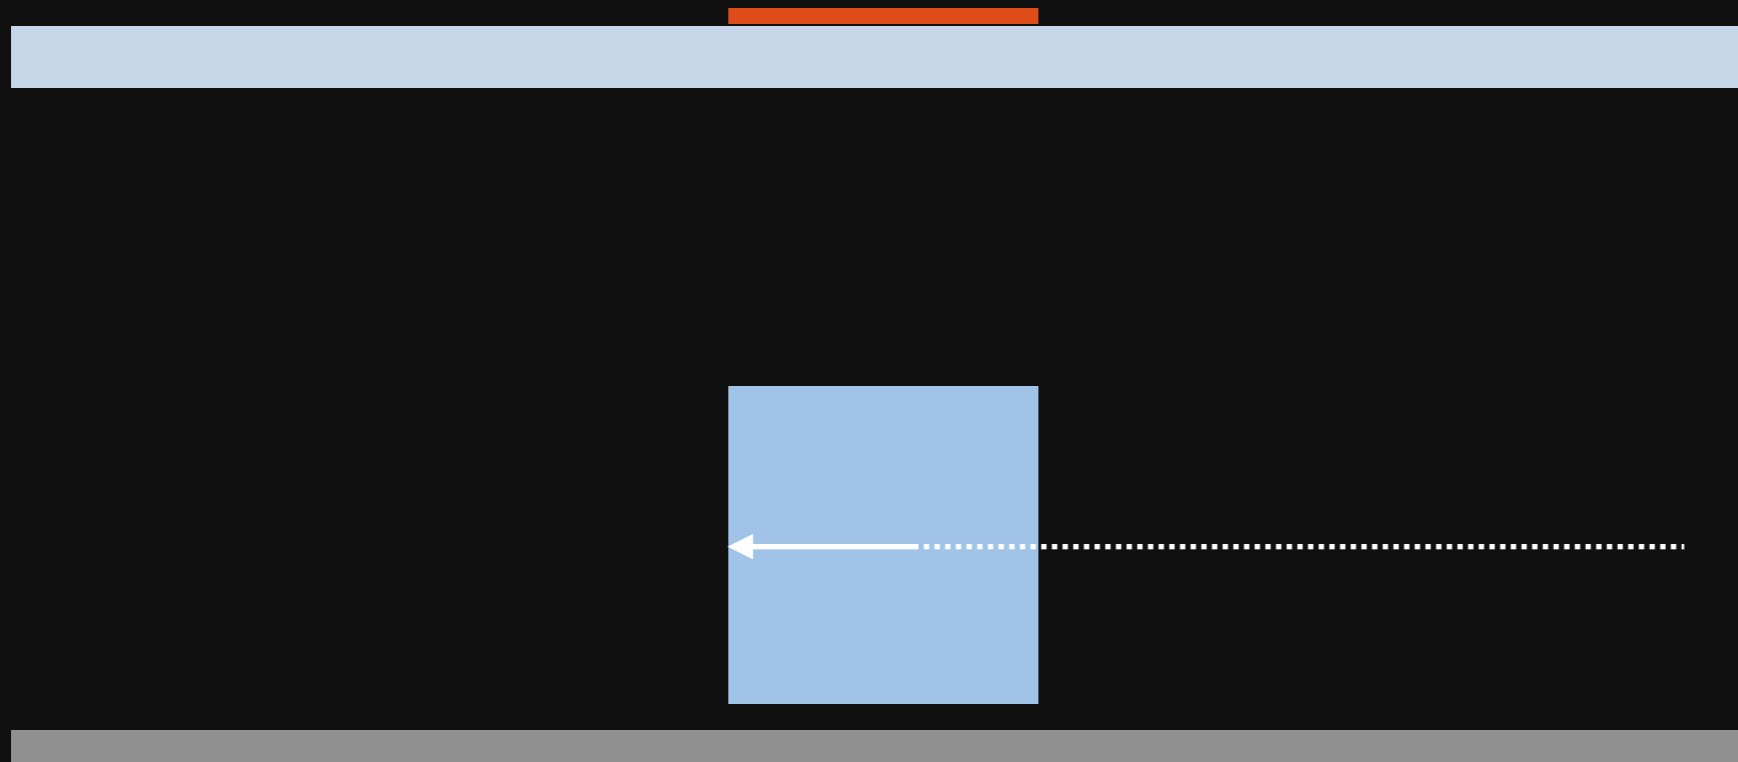

- ▶ “Starting Event” analysis provides a sample with very low background (from atm. neutrinos and muons)
- ▶ HE flux likely continues down to lower energies, hidden in the atm. background
- ▶ Pointing searches can tolerate a bit more background!

The Future

At the highest energies: “neutrino = extraterrestrial source”

- ▶ **We have a few nice starting tracks!**
 - ▶ e.g. “event #5” - starts three layers of strings inside the detector

The Future

How do we get more tracks?

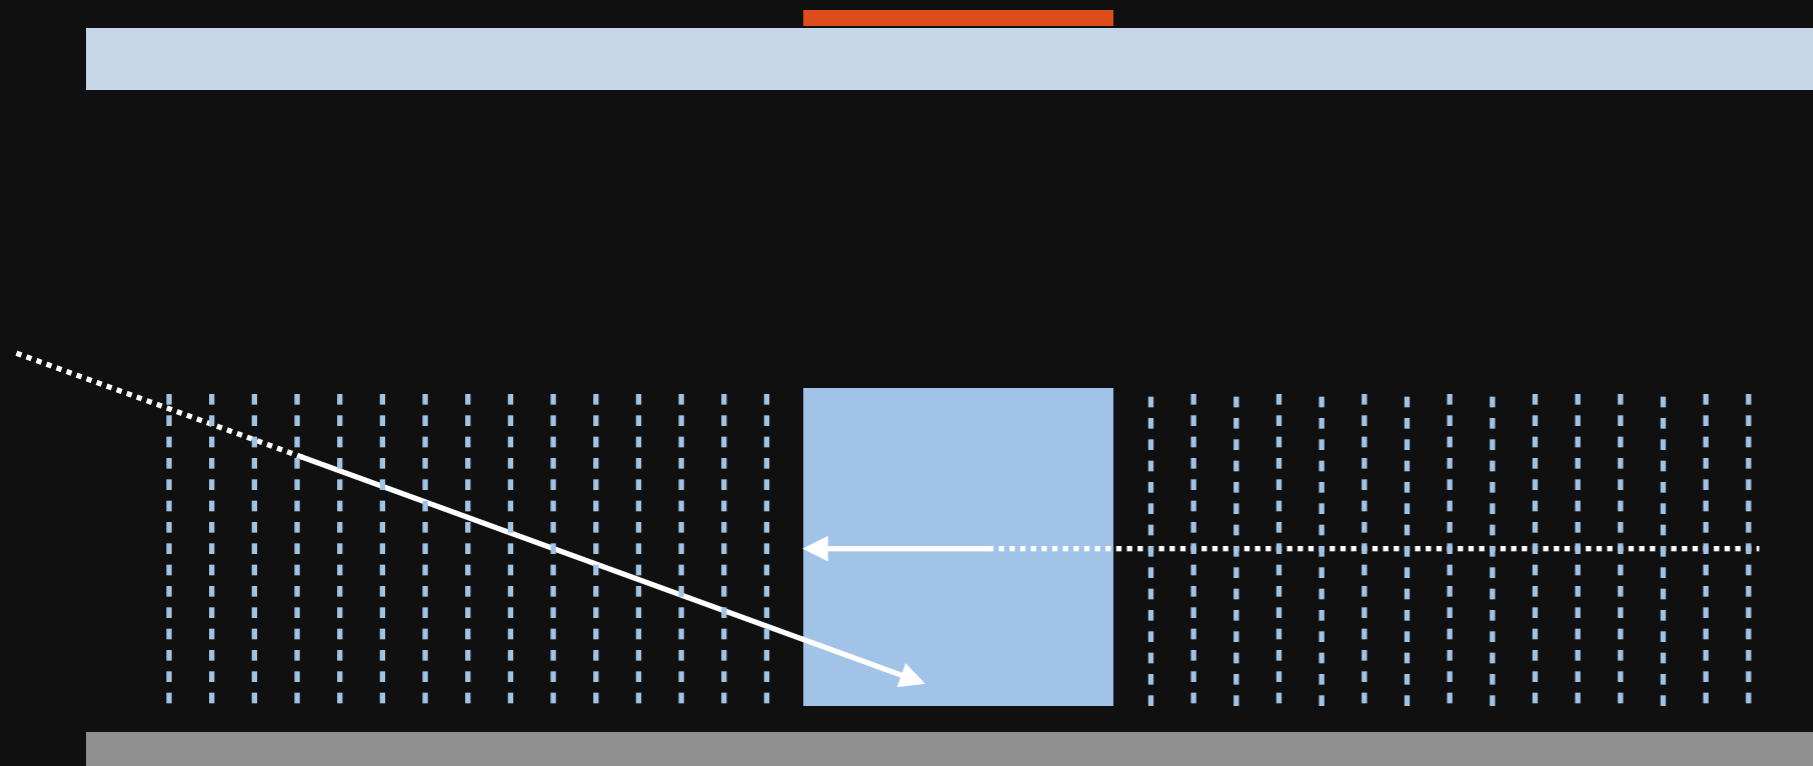

- ▶ **Add a large surface array, extending several km - can act as a CR veto**
 - ▶ enlarged volume for “starting” tracks

The Future

How do we get more tracks?

- ▶ **Add more strings, with wider spacing**
 - ▶ enlarges volume for starting tracks (and “ordinary” tracks)
 - ▶ long lever arm \rightarrow better resolution

The Future

How do we get more tracks?

- ▶ Or, of course, both!

The Future

R&D for a surface array

- ▶ **Similar to the current “IceTop” surface array**
 - ▶ using simplified versions of the current IceTop tanks
- ▶ **R&D is underway!**

The Future

An upgraded IceCube detector for high energies

- ▶ **Current threshold at about 1 TeV**
- ▶ **Can afford a slightly higher threshold of ~30 TeV**

Artist conception
Here: 120 strings at 300 m spacing

assuming ~100 new strings

The Future

An upgraded IceCube detector for high energies - in addition to low energies (PINGU!)

- ▶ **“Next generation” detector upgrade, extending the energy range**
- ▶ **PINGU**
 - ▶ **O(40) densely packed strings**
 - ▶ **Neutrino mass hierarchy, neutrino physics, dark matter,...**
- ▶ **“High-Energy Upgrade” (to be named)**
 - ▶ **O(100) strings, 5-10 km³**
 - ▶ **Identify astrophysical sources of neutrinos (and cosmic rays!), neutrino and particle physics**
- ▶ **Surface component: veto downgoing background, CR physics,...**

Neutrino and Muon Fluxes

Signal region begins to dominate above $\sim 80\text{TeV}$

Geometries

All upgrades also include PINGU low-energy strings (not shown) — these use the current IceCube technology (1x large PMT modules)

IceCube

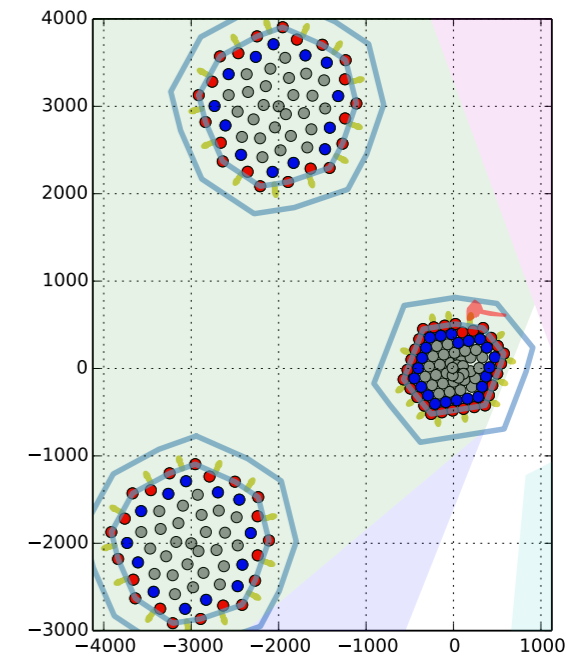

top area (+60m border): 0.9km^2
 volume: 0.9 km^3
 strings: IC86
 spacing: $\sim 125\text{m}$

“Sunflower”

top area (+60m border): 5.3km^2
 volume: 6.9 km^3
 strings: IC86+96
 spacing: $\sim 240\text{m}$

“Clusters”

top area (+60m border): 5.6km^2
 volume: 7.3 km^3
 strings: IC86+2x60
 spacing: $\sim 240\text{m}$

Angular Resolution

for muons entering the detector (at fixed muon energies)
(loose quality cuts)

Angular Resolution

for muons entering the detector (at fixed muon energies)
(loose quality cuts)

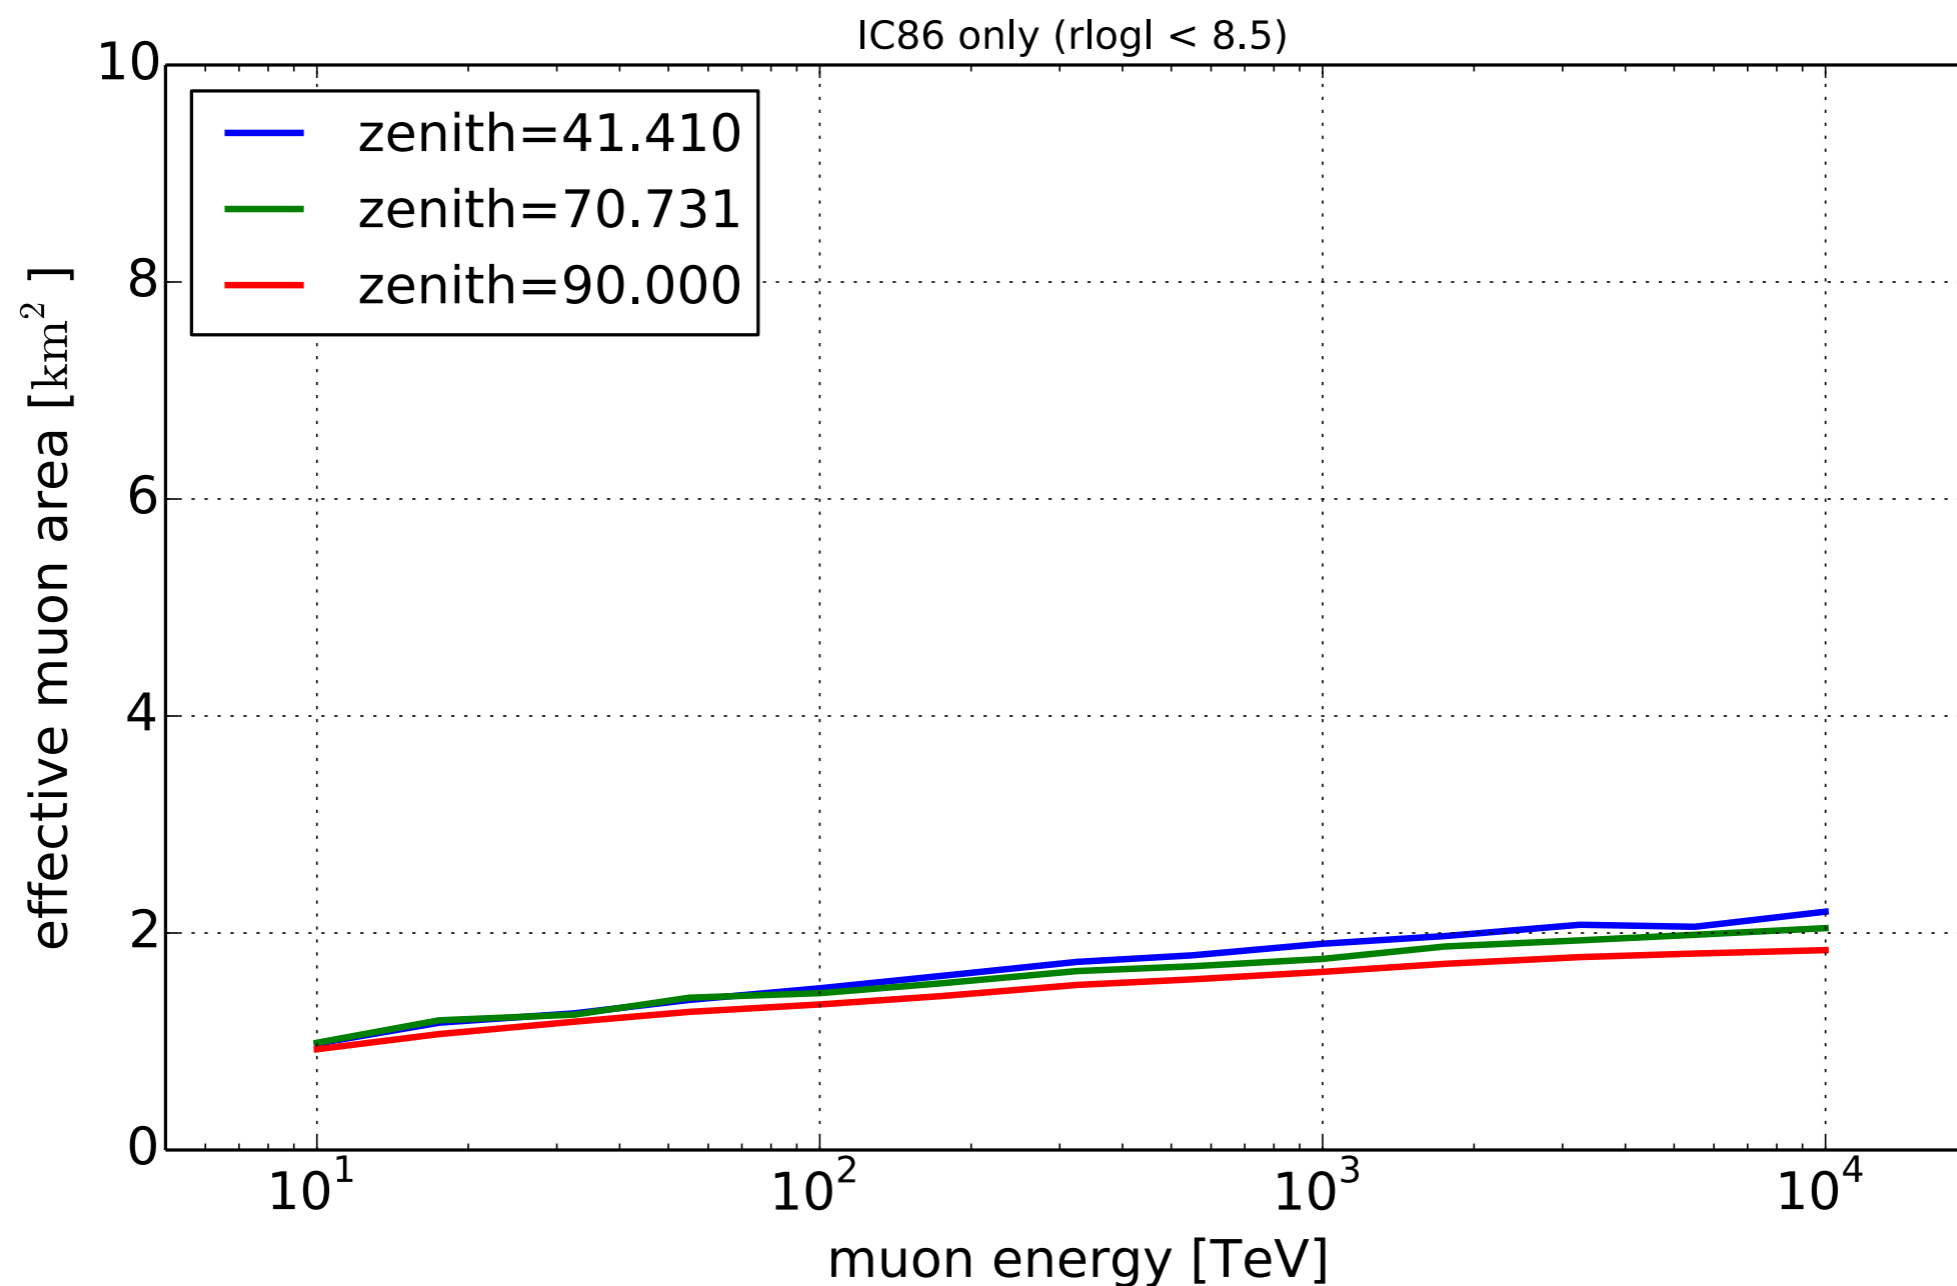

Angular Resolution

for muons entering the detector (at fixed muon energies)
(loose quality cuts)

Effective Area (muons)

for muons at fixed energies, loose cuts

Effective Area (muons)

for muons at fixed energies, loose cuts, accounting for 1.3km-long strings with ~ 80 DOMs per string

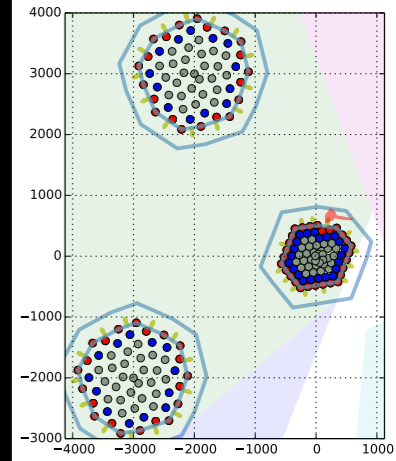

Effective Area (muons)

for muons at fixed energies, loose cuts, accounting for 1.3km-long strings with ~ 80 DOMs per string

Effective Area (muons)

for muons at fixed energies, loose cuts, accounting for 1.3km-long strings with ~ 80 DOMs per string

Conclusions

Stay tuned!

- ▶ **36(+1) events with energies above ≈ 50 TeV found in three years of IceCube data**
- ▶ **We see this in other channels (incoming muons) and down to energies of 10 TeV now!**
- ▶ **Statistics are steadily increasing, we are now working on characterizing the flux better and better**
- ▶ **We are planning future upgrades to measure this even better and look for the sources of these neutrinos!**

2 PeV event - “Big Bird”

Backup

Hint in Upgoing Muons

Study using the “IC59” partial detector during construction: 1.8σ

arXiv:1302.0127

Another Hint in Showers

Study using the “IC40” partial detector during construction: 2.4σ

GZK Neutrino Analysis

Simple search to look for extremely high energies (10^9 GeV) neutrinos from proton interactions on the CMB

▶ Upgoing muons

- Always neutrinos
- Background: atm. neutrinos
- High threshold (1 PeV)

▶ Downgoing muons (VHE)

- Cosmic Ray muon background
- Very high threshold (100 PeV)

Event Reconstruction

Generic full-sky likelihood scan for each event (works with shower and track signatures)

track

shower

- ▶ Fits for deposited energy along a “track” in each skymap direction based on hit pattern using a detailed model of the glacial ice optical properties
- ▶ Result: direction with uncertainty and estimate for deposited energy

Systematics in Energy Reconstruction

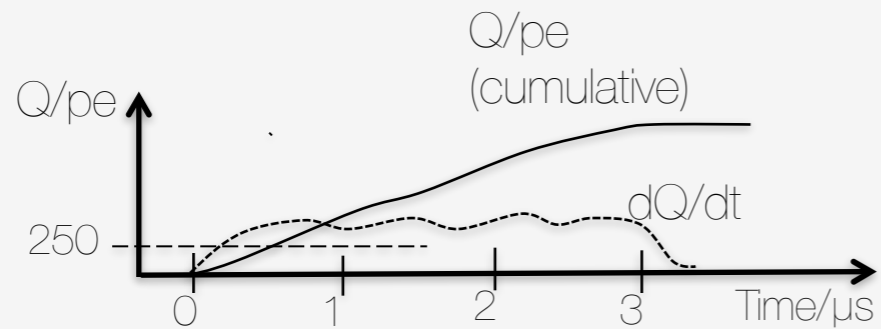

- ▶ **Energy scale: better than $\approx 10\%$**
 - From minimum ionizing muons: $\pm 5\%$
 - Scales very well to higher energies over orders of magnitude (measured with in-ice calibration laser)
- ▶ **Modeling of photon transport in ice**
 - Measured with in-ice calibration LEDs and other devices (dust logger, ...)
- ▶ **Statistical error at 1 PeV is negligibly small**

Background 1 - Atmospheric Muons

What's "early charge"?

Throughgoing muon

Total detector

Veto region

T_{250} = time at which $Q = 250$ pe

Contained cascade

Total detector

Veto region – barely contained cascade

Veto region – well contained cascade

T_{250} = time at which $Q = 250$ pe

Estimating Muon Background From Data

Use known background from atmospheric muons tagged in an outer layer to estimate the veto efficiency

- ▶ **Add one layer of DOMs on the outside to tag known background events**
 - Then use these events to evaluate the veto efficiency
- ▶ **Avoids systematics from simulation assumptions/models!**
- ▶ **Can be validated at charges below our cut (6000 p.e.) where background dominates**

Effective Area

Differences at low energies between the flavors due to leaving events at constant charge threshold

Systematic Studies and Cross-Checks

▶ **Systematics were checked using an extensive per-event re-simulation**

- varied the ice model and energy scale within uncertainties for each iteration and repeated analysis

▶ **Different fit methods applied to the events show consistent results**

▶ **Tracks:**

- good angular resolution (< 1 deg)
- inherently worse resolution on energy due to leaving muon

▶ **Showers:**

- larger uncertainties on angle (about 10° - 15°)
- good resolution on deposited energy (might not be total energy for NC and ν_τ)

Systematic Studies and Cross-Checks

Cross-check with a fit method based on direct re-simulation of events

- ▶ **Second fit method based on continuous re-simulation of events**
 - Can include ice systematics like directional anisotropy in the scattering angle distribution and tilted dust layers directly in the fit!
 - Very slow, works for shower-like events
- ▶ **Shown: comparison with other method**
- ▶ **Within these known bounds: all results are compatible to within 10%**

Event Distribution in Detector

Uniform in fiducial volume

Event Distribution in Detector

Uniform in fiducial volume

Event Distribution in Detector

Uniform in fiducial volume

- ▶ **Backgrounds from atm. muons would pile up preferentially at the detector boundary**
- ▶ **No such effect is observed!**

Events Selection

Charge in veto region vs. total charge

Fluxes and Limits

Fluxes normalized to 3 flavors (1:1:1) except atm. neutrinos

Atmospheric Neutrino Spectrum

Measured with IceCube in ν_μ and ν_e
