Outline

Brief overview of planet formation around single stars

Motivation for this study

Planet formation in the α Centauri AB binary system

Planet formation around very close binary stars

Current status

Solar Nebula Theory

(Kant 1755, Laplace 1796)

The Planets Formed in a Disk in Orbit About the Sun

Explains near coplanarity and circularity of planetary orbits

Disks are believed to form around most young stars

Theory: Collapse of rotating molecular cloud cores

Observations: Proplyds, β Pic, IR spectra of young stars

Predicts planets to be common, at least about single stars

Planetesimal Hypothesis

(Chamberlain 1895, Safronov 1969)

Planets Grow via Binary Accretion of Solid Bodies

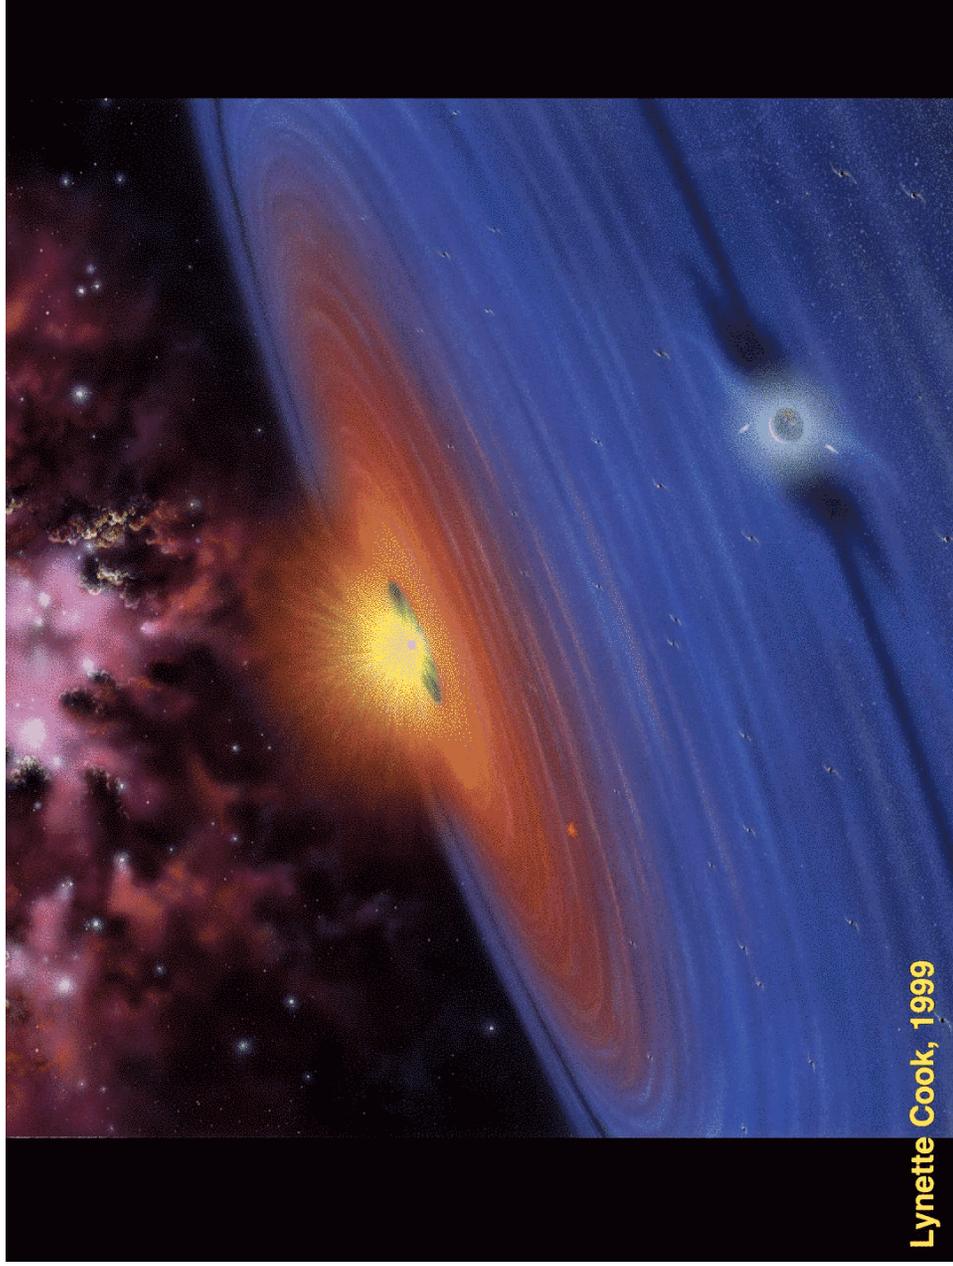

Massive Giant Planets Gravitationally Trap

$H_2 + He$ Atmospheres

Explains planetary composition vs. mass

General; for planets, asteroids, comets, moons

Can account for Solar System; predicts diversity

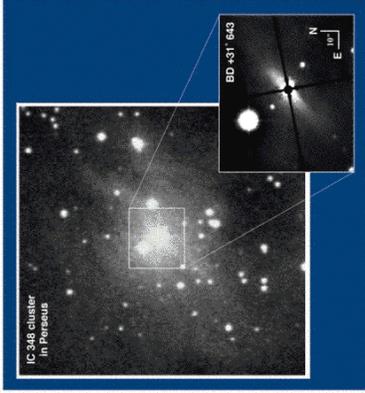

Motivation

> 50 % stars are in multiple star systems (Duquennoy & Mayor 1991)

19 planets known in multiple star systems (Eggenberger et al. 2004)

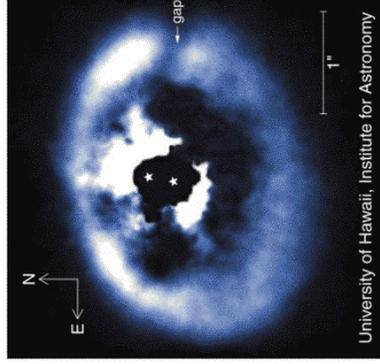

What is the effect of a stellar companion on the planet formation processes?

Dust Disks Around Young Binaries

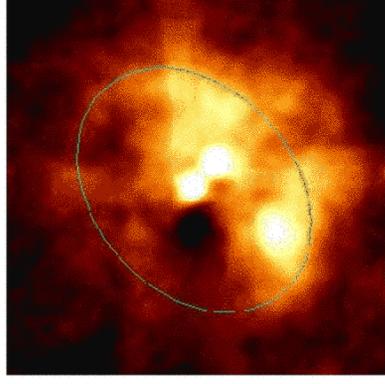

← BD +31 643

a_B (stellar semimajor axis) ~ 40 AU

UY Aur
↓ $a_B \sim 130$ AU

GG Tauri →
 $a_B \sim 35$ AU
 $180 \text{ AU} < r_{\text{disk}} < 260 \text{ AU}$

$a_B < 1 \text{ AU}$

GW Ori (disk mass $m_D \sim 0.3 M_{\text{sun}}$)
DQ τ ($m_D = 0.02 M_{\text{sun}}$)
UZ τ E ($m_D = 0.06 M_{\text{sun}}$)

Planet Formation

Early stage

dust grains $\sim \mu\text{m}$ → planetesimals $\sim 1\text{-}10 \text{ km}$

Middle stage

planetesimals → planetary embryos $\sim 10^3 \text{ km}$

Late stage

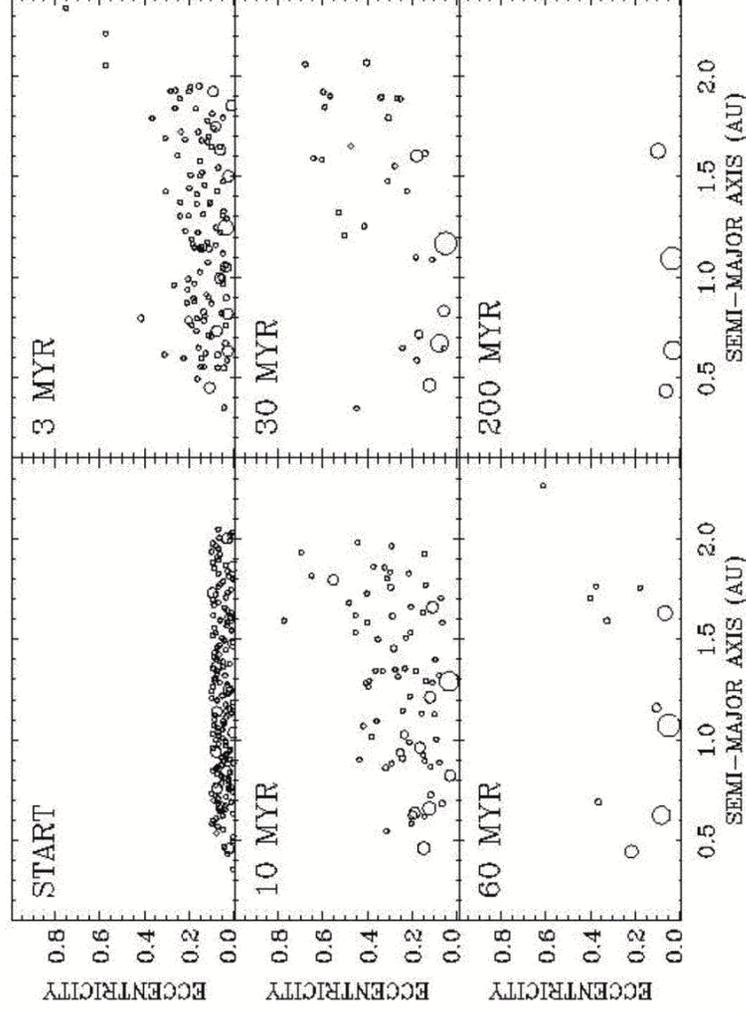

embryos → planets

Accretion in the Solar System

Chambers (2001) - Terrestrial planet accretion in the Solar System

- Bimodal mass distribution (0.3 - 2.0 AU):
 - 14 large embryos ($0.0933 M_{\text{Earth}}$)
 - 140 smaller planetesimals ($0.00933 M_{\text{Earth}}$)
 - Randomized e (0.0 - 0.01), i (0 - 0.5), ω , Ω , M
 - Early formed Jupiter and Saturn
 - *Mercury5* Hybrid-symplectic integrator (inelastic collisions)
- ~4 terrestrial planets formed within 200 Myr with above conditions

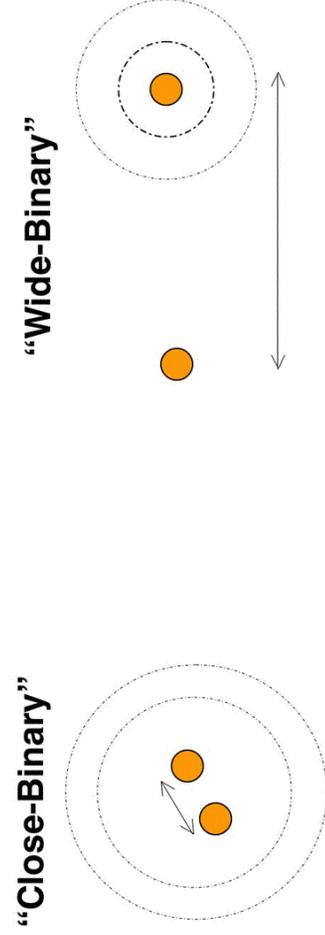

Terrestrial Planet Growth Sun-Jupiter-Saturn (Chambers 2001)

Methodology

Symplectic integrators: widely used algorithms to study long-term behavior of N-body systems with a dominant central mass

- Based on mapping method of Wisdom & Holman (1991)
 - order of magnitude faster than conventional integrators
 - no secular changes in energy of system
- Modified to include 2nd dominant mass (Chambers et al. 2002):

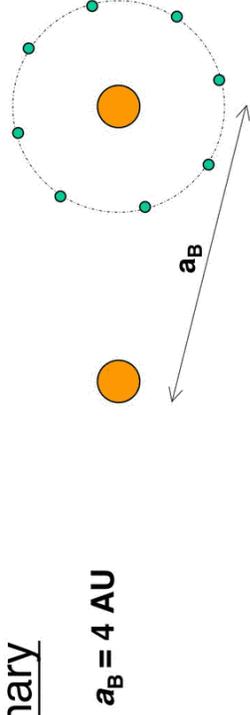

Tests of New Algorithms

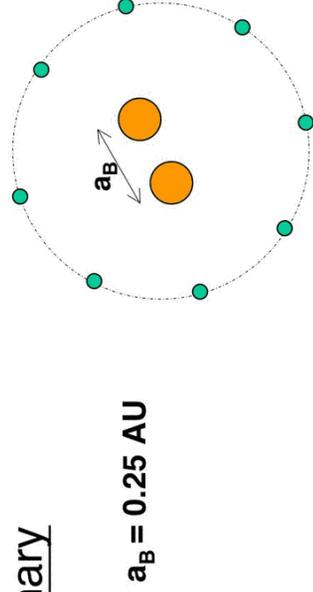

1. Conservation of Jacobi constant
2. Massless particles orbiting α Cen A
3. Integrations of Mercury through Jupiter with Saturn as 'binary companion'
4. Terrestrial planet accretion simulations with Jupiter as 'binary companion'

Test #1: Conservation of Jacobi Constant

Wide-binary

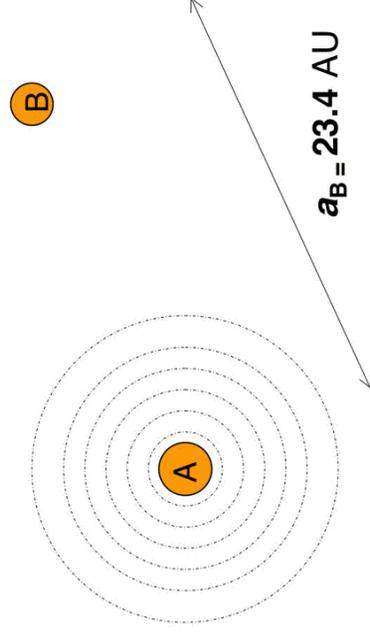

Close-binary

Test #2: Particles around α Centauri A

Reproduce the results of Weigert & Holman (1997)
(50 massless particles between 0.2 - 11.7 AU from α Cen A)

Compute a_c = critical semimajor axis using widebinary code

Test #3: Six Solar System Planets

- Integration of Mercury with Saturn = 'binary' Jupiter for 1 Myr

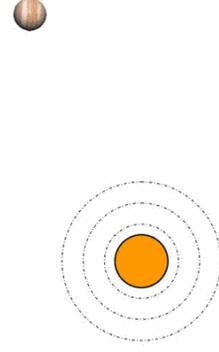

Using 3 symplectic integrators:

- 'Wide-binary'
- Standard code #1 ('Symba')
- Standard code #2 ('Hybrid')

- Compare evolution of planets' eccentricities with very accurate (but slow) integrator (RADAU)

Test #4: Terrestrial Planet Accretion

- ~ 150 Embryos around Sun
Jupiter = 'binary'

- 3 simulations:
 - Standard 'Hybrid' code
 - New binary code
 - New binary code with one embryo (near 1AU) shifted along its orbit by 1 meter (to test relative importance of chaos vs. different integrators)

Circumstellar Disk

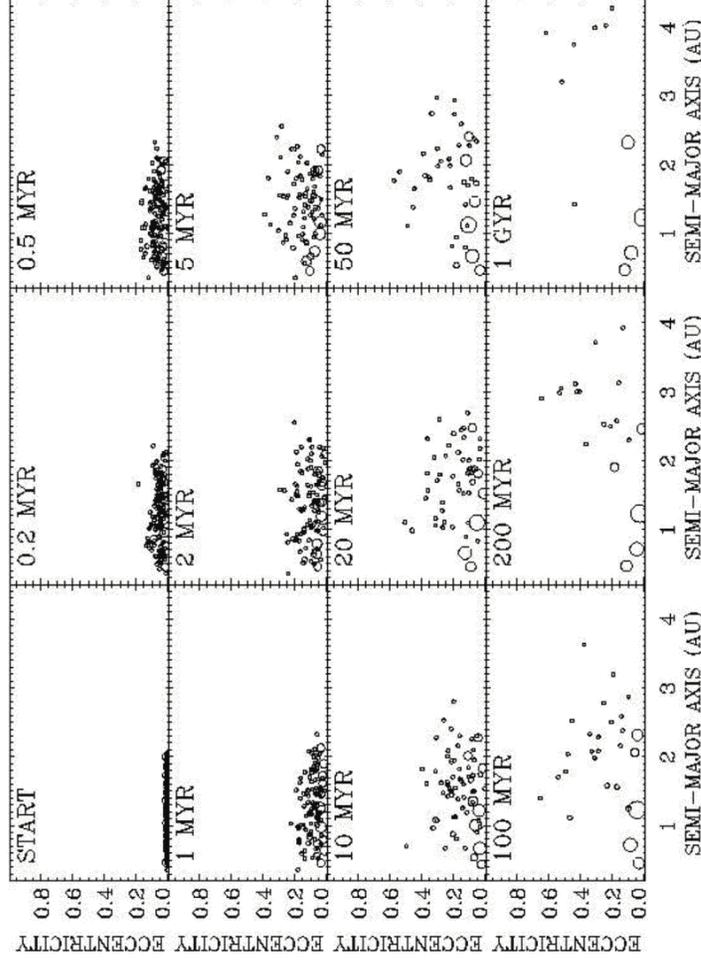

Disk mass distribution adopted from Chambers (2001) accretion simulations in the Sun-Jupiter-Saturn system

- #1** - Bimodal mass distribution
 - 14 large embryos ($0.0933 M_{\text{Earth}}$)
 - 140 smaller planetesimals ($0.00933 M_{\text{Earth}}$)
 - $a = 0.3 - 2.0$ AU
 - Random e ($0.0 - 0.01$), i ($0 - 0.5^\circ$), ω , Ω , M

To examine effects of chaos, each simulation was performed 2 - 4 times with:

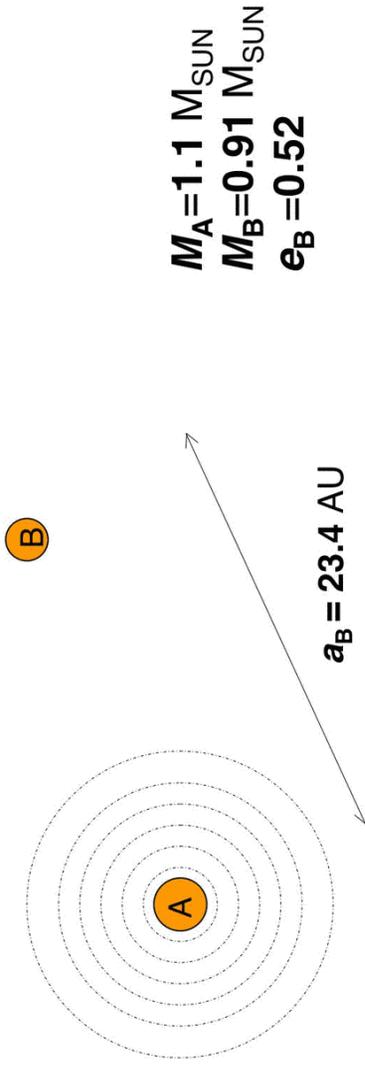

- #2** - Bimodal mass distribution (as above)
 - 1, 2 or 3 meter shift in mean anomaly of one planetesimal

RUN 1 ($i = 0^\circ$) Single Star, no giant planets

Stable Orbits in the α Cen System

Weigert & Holman (1997) showed that massless particles placed on circular orbits in the binary midplane within 3 AU of α Cen A remain on bound orbits for at least 2.5 Myr.

Planetesimal Accretion in α Cen

Marzari & Scholl (2000) - Planetesimal accretion in α Cen

- ~ 5000 planetesimals (0.8 - 3.0 AU) coplanar with binary orbital plane (bidimensional)
- inelastic collisions and gas drag forces, no gravitational interactions among planetesimals
- 4th-order Runge-Kutta integrator

Planetesimal accretion possible within 2 AU of α Cen A

α Cen - Initial Conditions

- Bimodal mass distribution around α Cen A
- Binary star inclined at $i = 0, 15, 30, \text{ or } 60^\circ$
argument of periastron $\omega = 0 \text{ or } 90^\circ$
- Identical systems with one planetesimal ~ 1 AU shifted by 1 m
- Widebinary symplectic integrator (inelastic collisions)
- 200 Myr - 1 Gyr integrations

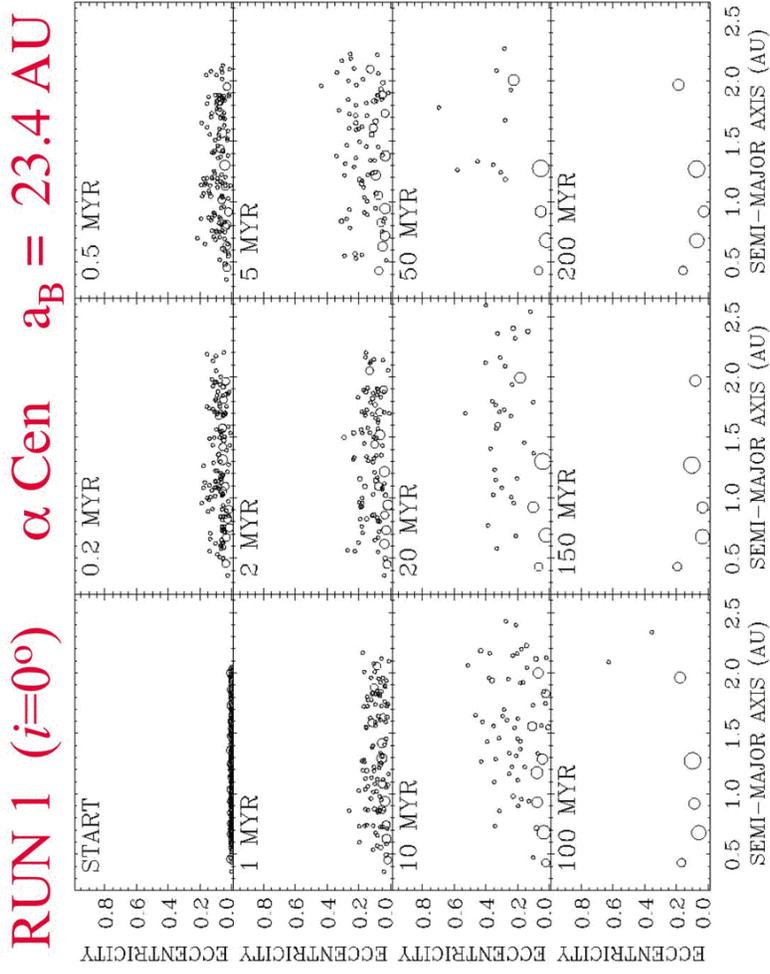

α Centauri System

G2 star
 $M = 1.1$ Msun

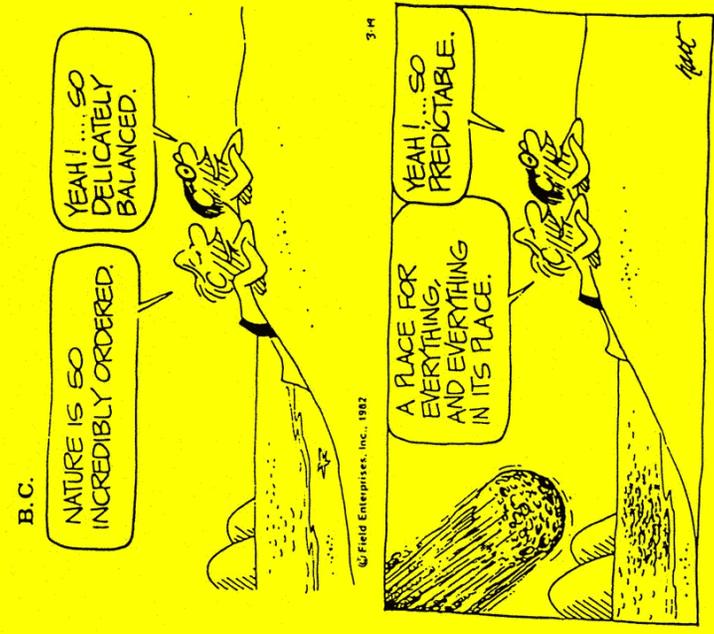

K1 star
 $M = 0.91$ Msun

- Disk inclined to binary orbit:
 $i = 0^\circ, 15^\circ, 30^\circ, 45^\circ, 60^\circ, 180^\circ$
- Integration time = 200 Myr - 1 Gyr
- Time-step = 1 - 7 days

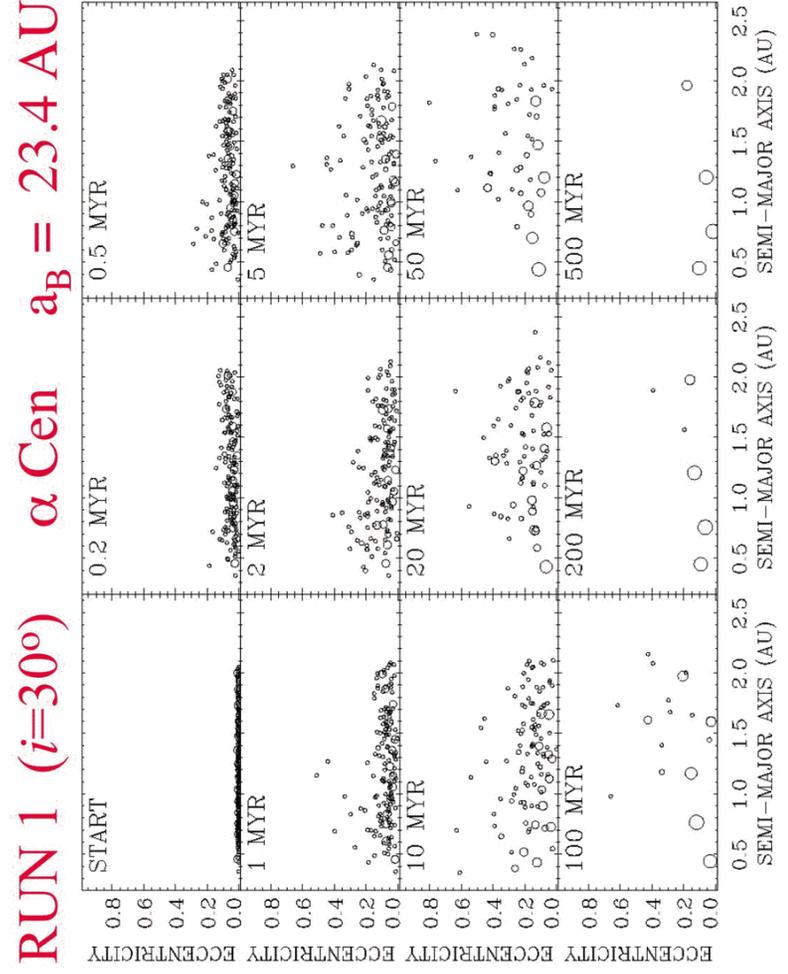

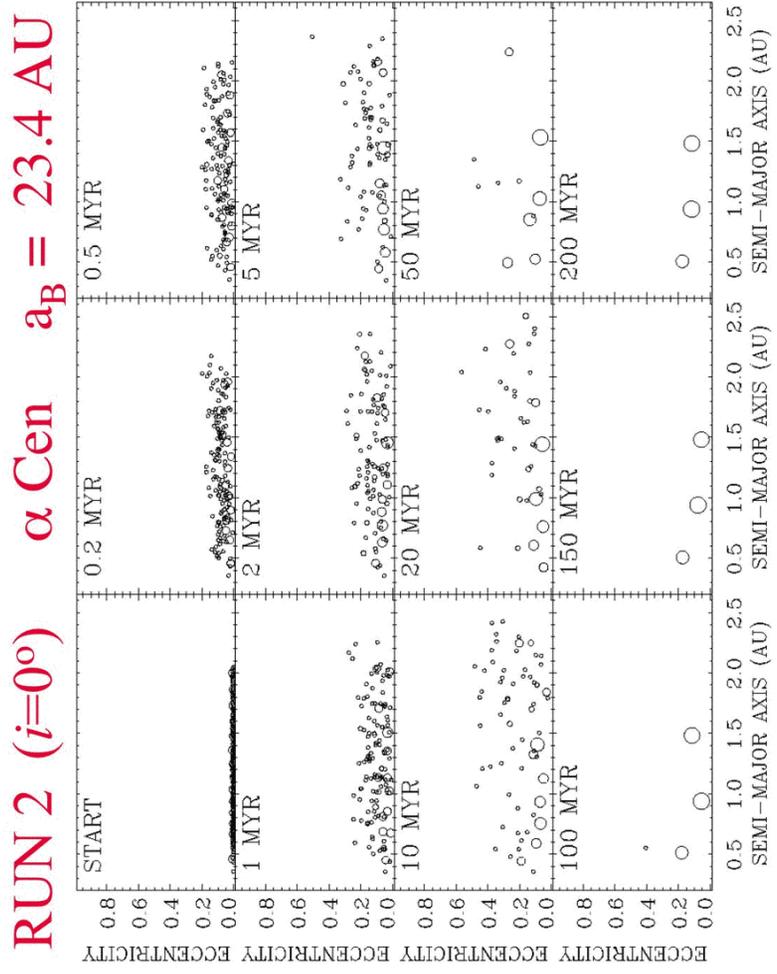

Planet formation is $Chaos$, so many numerical experiments are needed to get statistically valid results.

3-14

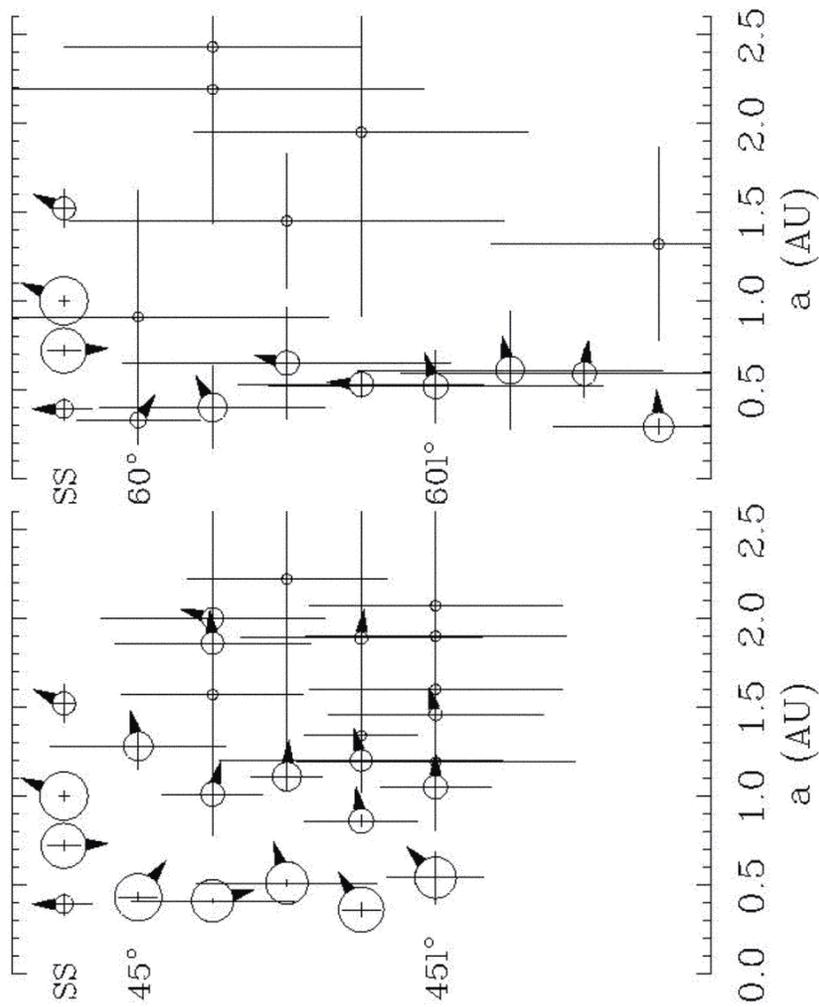

RUN 1 ($i=180^\circ$) α Cen $a_B = 23.4$ AU

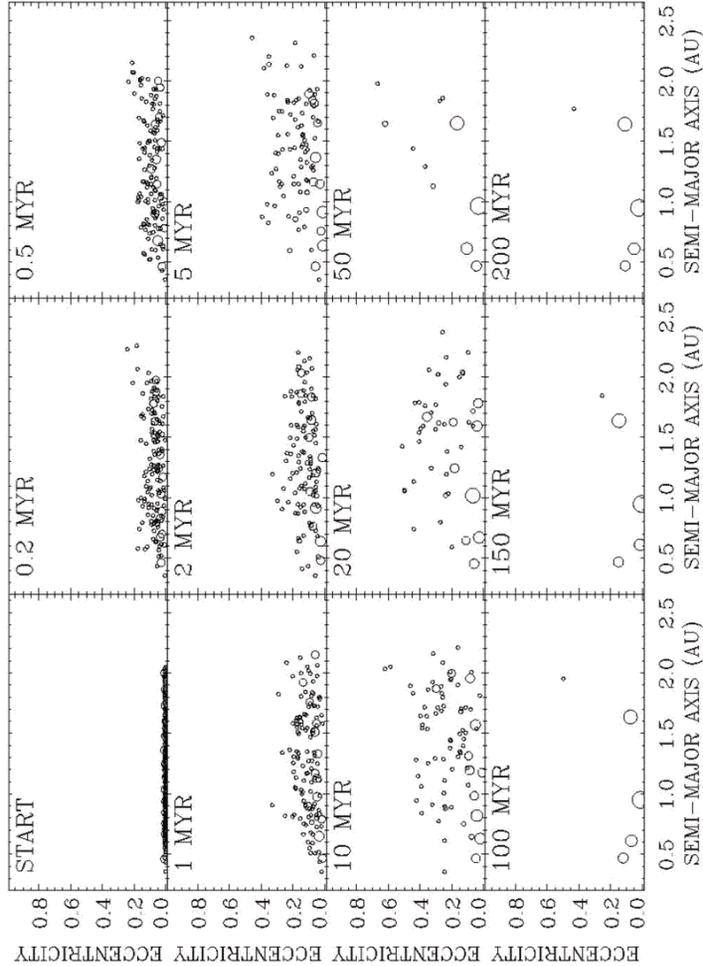

Final Terrestrial Planets Orbiting α Cen A

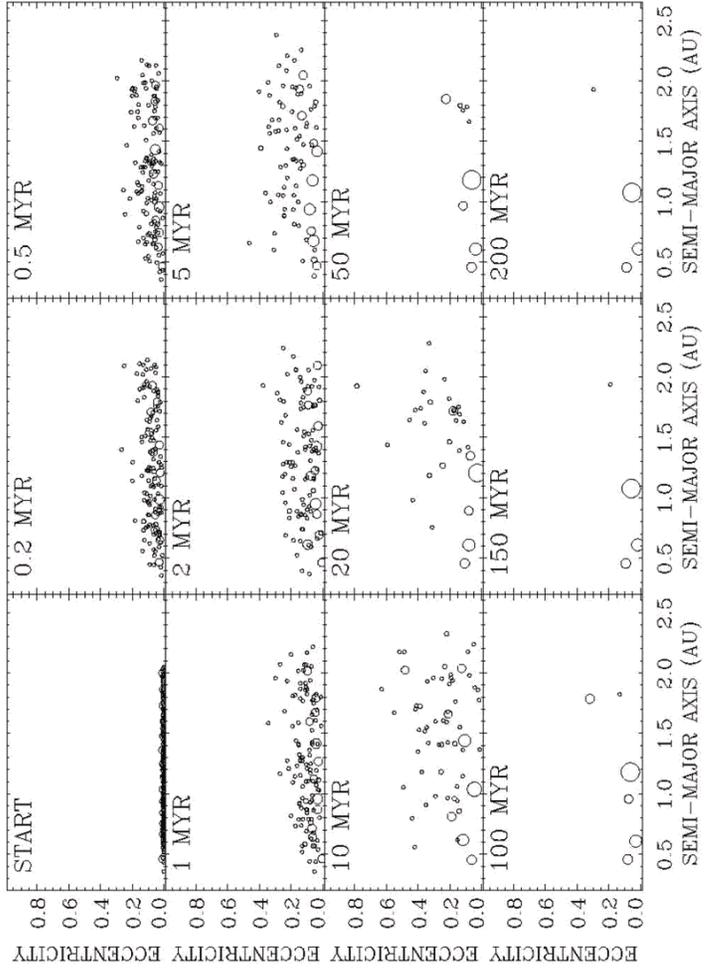

Final Planets Orbiting α Cen A (high i disks)

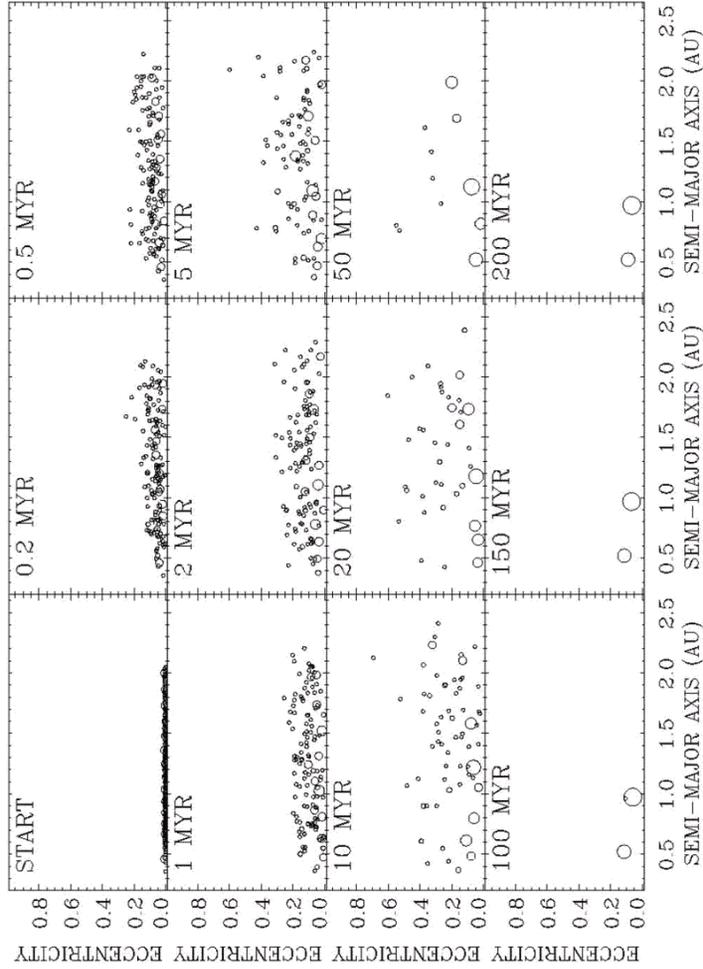

α Centauri B, Run 1 ($i = 0$)

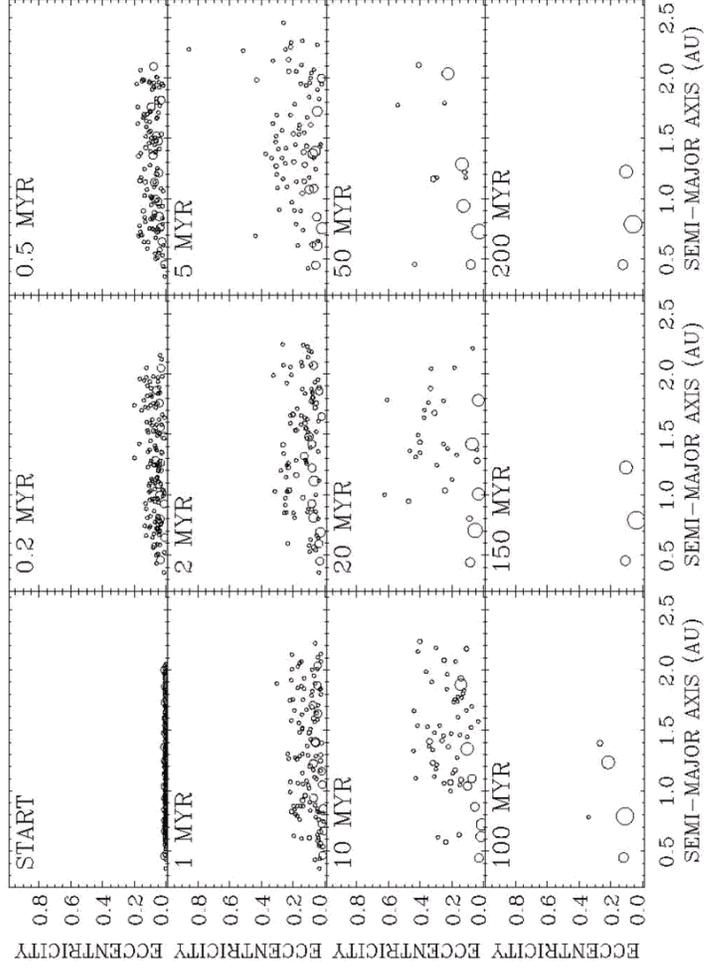

α Centauri B, Run 2

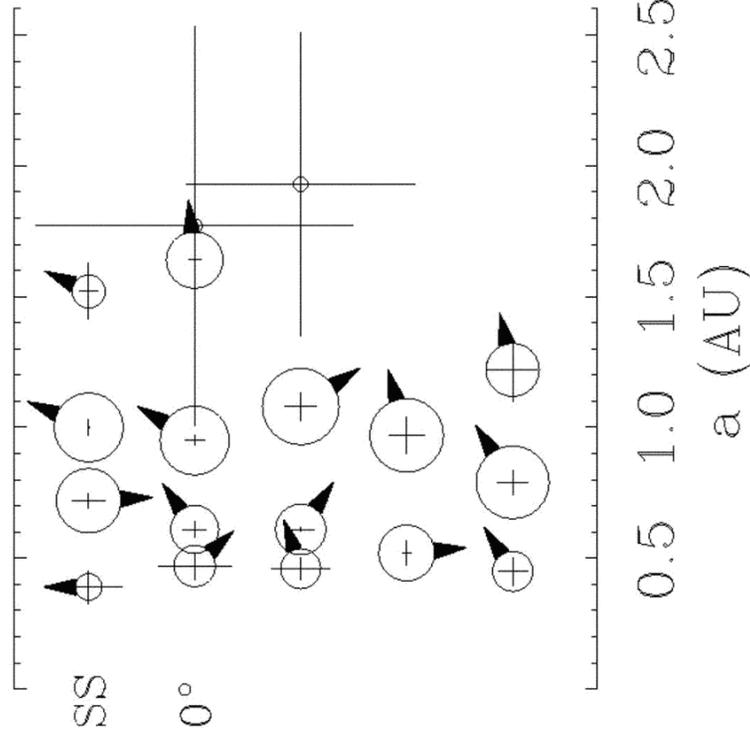

α Centauri B, Run 3

α Centauri B, Run 4

Final Planets Orbiting α Cen B

Results: α Centauri System

Planetesimal disk near plane of binary orbit: $i_{\text{disk}} \leq 30^\circ$

- 3 - 5 terrestrial planets formed
- < 25% of initial disk mass lost
- similar to our Solar System

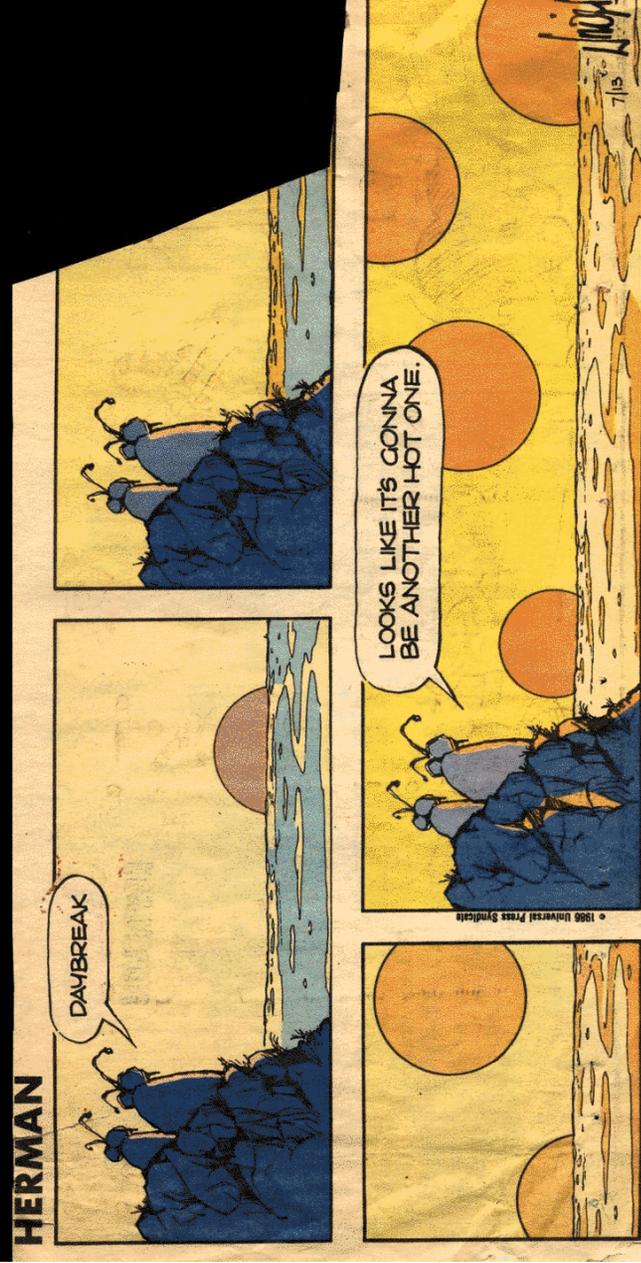

Accretion much less efficient as i_{disk} increased:

$i_{\text{disk}} = 45^\circ$: ~ 60% of initial disk mass lost

$i_{\text{disk}} = 60^\circ$: ~ 98% of initial disk mass lost

Terrestrial planets may have formed around α Cen A and/or around α Cen B, despite the proximity of these two stars.

Planets, yes! But life?

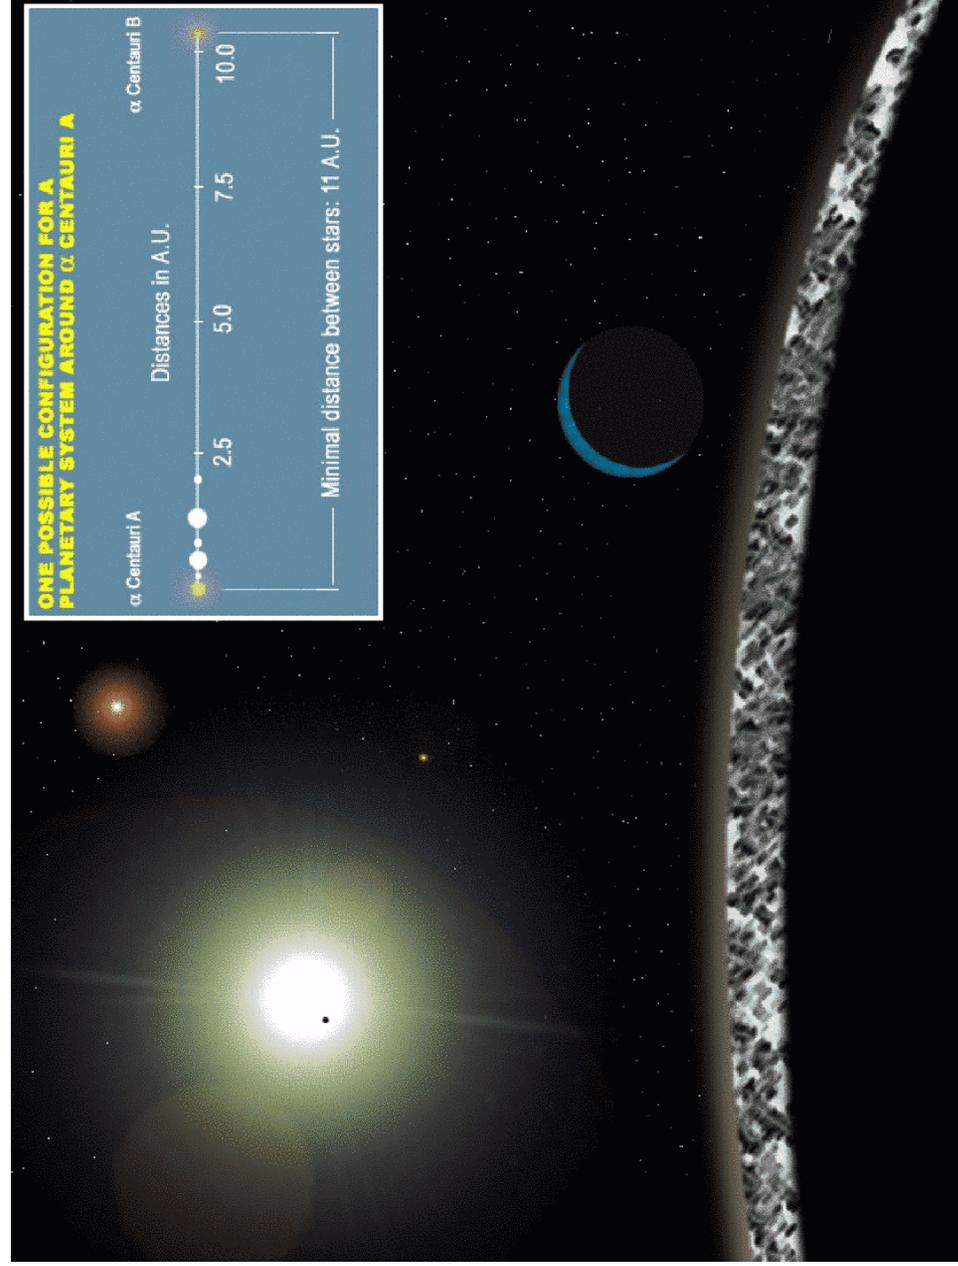

Volatiles and Habitability

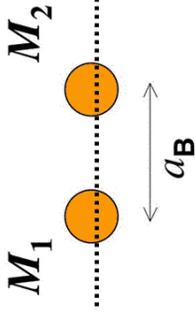

If planets formed around α Centauri A and/or α Cen B, would such planets be habitable?

Probably not. Models for delivery of volatiles (Morbidelli et al. 2000) suggest terrestrial planets receive volatiles primarily from the asteroid belt and beyond. In the α Cen system, orbits > 3 AU from α Cen A or B are very unstable, and material would not form planetesimals in these regions.

α Centauri may thus have **dry terrestrial planets**, devoid of the C/H₂O-based life which thrives on Earth.

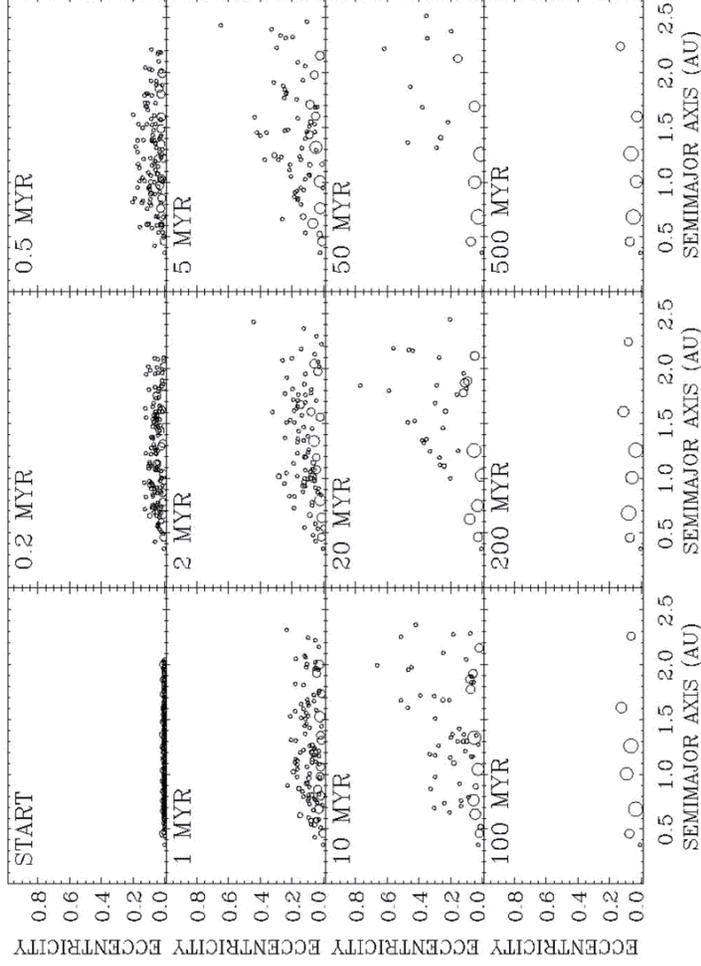

Close Binary Systems

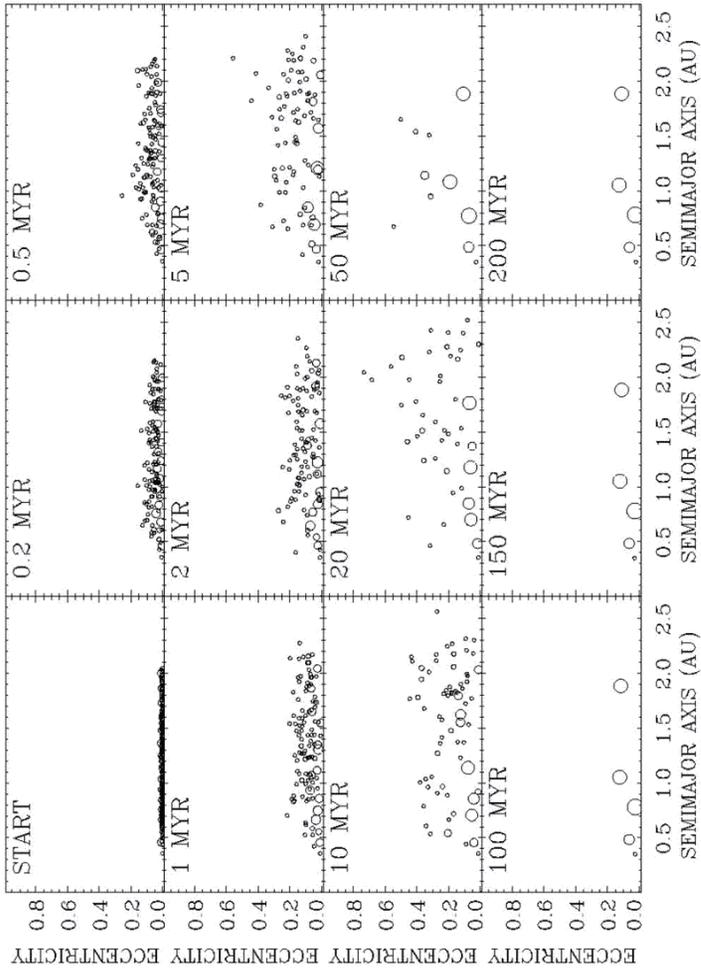

- $a_B = 0.05, 0.075, 0.1, 0.15, 0.2, 0.3, 0.4$ AU
- $e_B = 0.0, 0.33, 0.5, 0.8$
- $i_B = 0^\circ, 30^\circ$
- Mass Ratio $\mu = M_2 / (M_1 + M_2) = 0.5$ or 0.2
- Integration time = 200 Myr - 1 Gyr

Final Planetary Systems

Planetary Statistics

Derived to quantify characteristics of planetary systems formed

N_p = # planets at least as massive as Mercury
($\sim 0.06 M_{\oplus}$)

N_m = # planets less massive than Mercury

S_m = Fraction of the total (final) mass in the largest planet

For the Solar System terrestrial planets (MVEM), $S_m = 0.51$
(more than half of the mass resides in Earth)

Orbital Spacing Statistic

$$S_s = \frac{6}{N_p - 1} \left(\frac{a_{\max} - a_{\min}}{a_{\max} + a_{\min}} \right) \left(\frac{3 M_*}{2 m} \right)^{1/4}$$

\bar{m} = mean mass of the final planets

M_* = total mass of the binary stars

a_{\max}, a_{\min} = max and min semimajor axes

Angular Momentum Deficit

$$S_d = \frac{\sum_j m_j \sqrt{a_j} [1 - \sqrt{1-e_j^2}] \cos i_j}{\sum_j m_j \sqrt{a_j}}$$

For j planets

- a measure of the fractional difference between the planets' actual orbital angular momenta and the angular momenta that they would have on circular uninclined orbits with the same semimajor axis

Mass Concentration Statistic

$$S_c = \max \left\{ \frac{\sum_j m_j}{\sum_j m_j [\log_{10}(a/a_j)]^\beta} \right\}$$

For j planets

- a measure of the degree to which mass is concentrated in one part of the planetary system

Radial Mixing Statistic

$$S_r = \left(\sum_j m_j \frac{|a_{init,j} - a_{fin,j}|}{a_{fin,j}} \right) / \sum_j m_j$$

For j planets

$a_{init,j}$ and m are the initial semimajor axis and mass of each embryo that becomes incorporated into a final planet
 $a_{fin,j}$ is the semimajor axis of the final planet

- a sum of the radial migrations of the bodies that form a planet

Table 1. A summary of the planetary statistics for our close-binary (CB) simulations are shown in blue (in the form CB_ a_B - e_B - m), followed by statistics for the (actual and simulated) Solar System.

Results

Close binary stars with low e_B and $a_B = 0.05$ or 0.1 AU produce planetary systems similar to simulations of the Solar System.

Binary stars with a moderately eccentric orbit tend to produce fewer (2 - 3) planets.

Planetary accretion is less effective around binary systems with $e_B > 0.2$ or $a_B > 0.2$ AU.
