

ITP/Santa Barbara, April 2002

The free energy of hot QCD

K. Kajantie (Helsinki)

1. Free energy of QCD up to $T \approx 10T_c$ from 4d (τ, \mathbf{x}) lattice Monte Carlo: $f(T, T/\Lambda_{\text{QCD}}; N_c, N_f)$
2. Free energy of QCD from $\approx 3T_c$ to T_{Planck} from effective theories and 3d (\mathbf{x}) lattice Monte Carlo
3. Effective degrees of freedom in equilibrium QCD plasma at $T \gtrsim 3T_c$ are gluons with up to 4loop interactions; the nonperturbative constant seems small for p (is large for, say, Debye mass)

Note: Same methods solve electroweak *phase transition*

$$\frac{g}{3} \ll 1 \ll 2$$

Joint work with K. Kajantie, M. Laine, K. Rummukainen, Y. Schröder, hep-ph/0007109 (PRL), hep-ph/0109100 (PRD)

M. Achammer

1. General definition

We know QCD:

$$\mathcal{L} = \frac{1}{4} F_{\mu\nu}^a F_{\mu\nu}^a + \sum_{N_f} \bar{\psi}_f \gamma_\mu (\partial_\mu + ig T_a A_\mu^a) \psi_f,$$

$$F_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a - gf_{abc} A_\mu^b A_\nu^c$$

Its free energy density ($= f = -p$) is

$$e^{-f(T,g)V/T} = \int \mathcal{D}A_\mu^a(\tau, \mathbf{x}) \mathcal{D}\bar{\psi} \mathcal{D}\psi e^{-\int_0^{1/T} d\tau \int d^3x \mathcal{L}[A_\mu^a, \bar{\psi}, \psi]}$$

so just compute this!

Bielefeld 1980-

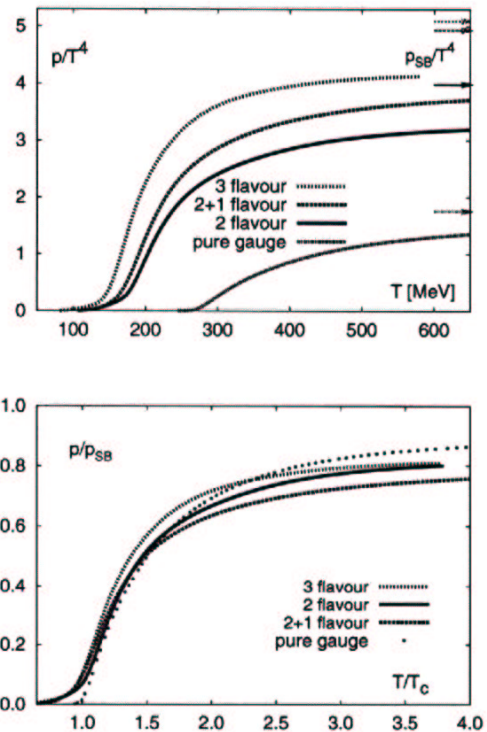

b.c. over τ are periodic (A_μ^a) or anti-periodic in the Grassmannian ($\bar{\psi}, \psi$).

Ideal gas:

$$-f(T, g=0) \equiv p_{\text{SB}}(T) = (16 + \frac{21}{2} N_f) \frac{\pi^2}{90} T^4.$$

A truly first-principle method for computing f is numerical lattice Monte Carlo:

Lattice: measure derivatives of F as expectation values, integrate back F by choosing $F/T = 0$ deep in hadronic phase (data from Bielefeld):

Note: at $T = T_c$

- $p(T_c) \approx 0$ for pure glue since glueballs very heavy
- $p(T_c) = p$ of (massless) pion gas for $N_f = 2 \dots 3$
- $p'(T_c)$ discontinuous \Rightarrow genuine phase transition

Related catch words:

Casimir effect:

Finite range in coordinates, now $0 < \tau < \hbar/T$

$$\Rightarrow \epsilon \sim T^4$$

Usually ideal gas in domain of some shape, now emphasis is on interactions

Cosmological constant:

The value of the functional integral is \sim the “cosmological constant” of our theory: we can only determine how it varies, but there is an overall unknown additive scale.

Two ranges of different equilibrium physics:

- $T_c \lesssim T \lesssim \text{few} \times T_c$: Relevant dofs (?): T -modified hadrons, instantons, monopoles, Polyakov line,...
- $T \gtrsim \text{few} \times T_c$: Relevant dofs (?): collective modes, *interacting* gluons

Static and dynamic dofs may be different!

The 1st principle 4dim lattice computation in practice only is feasible up to some $10T_c$:

$$a \ll \frac{1}{T} \ll \frac{1}{T_c} \approx \frac{1}{\Lambda_{\text{QCD}}} \approx 1\text{fm} \ll Na$$

At $10T_c$ and if \ll is a factor 1/4:

$$0.025\text{fm} < 0.1\text{fm} < 1\text{fm} < 4\text{fm}$$

Intractable multiscale problem!

HQET $Q\bar{q}$
NRQCD $\bar{q}q$

Why care about this? Just structureless $\approx 20\%$ below S-B!
But: this is most fundamental quantity in hot QCD, want to understand everything!

So what to do at $T > 2...3T_c$?

- 4d perturbation theory: sooner or later you hit the infrared wall; must use experiment (like in jet physics) or computers
- Organise the computation in a part in which perturbation theory works (derive 3d effective theories by integrating over excitations of mass $\sim \pi T, gT$) and a part which has to be treated numerically

Topologies of diagrams one has to evaluate (hepph0109100):

$$\begin{aligned}
 -F &= -F_0 + \Phi_2[\Delta] \quad c_{\text{boson}} = \frac{1}{2}, \quad c_{\text{fermion}} = -1 \\
 &+ \left(\Phi_3[\Delta] + \sum_i c_i \left(\frac{1}{2} \text{diagram} \right) \right) \\
 &+ \left(\Phi_4[\Delta] + \sum_i c_i \left(\frac{1}{3} \text{diagram} + \text{diagram} + \frac{1}{2} \text{diagram} \right) \right) \\
 &+ \left(\Phi_5[\Delta] + \sum_i c_i \left(\frac{1}{4} \text{diagram} + \text{diagram} + \frac{1}{2} \text{diagram} \right. \right. \\
 &\left. \left. + \frac{1}{2} \text{diagram} + \frac{1}{2} \text{diagram} + \text{diagram} + \frac{1}{2} \text{diagram} + \frac{1}{3} \text{diagram} \right) \right)
 \end{aligned}$$

The skeleton topologies are (up to 4loop):

$$\begin{aligned}
 \Phi_2 &= \frac{1}{12} \text{diagram} + \frac{1}{8} \text{diagram} \\
 \Phi_3 &= \frac{1}{24} \text{diagram} + \frac{1}{8} \text{diagram} + \frac{1}{48} \text{diagram} \\
 \Phi_4 &= \frac{1}{72} \text{diagram} + \frac{1}{12} \text{diagram} + \frac{1}{8} \text{diagram} + \frac{1}{4} \text{diagram} \quad \text{done!} \\
 &+ \frac{1}{8} \text{diagram} + \frac{1}{8} \text{diagram} + \frac{1}{16} \text{diagram} + \frac{1}{48} \text{diagram}
 \end{aligned}$$

FORM program; Y. Schröder :

Here are the 5loop skeletons, for your enjoyment;

$$\begin{aligned}
 \Phi_5 = & \frac{1}{4} \text{[diagram]} + \frac{1}{48} \text{[diagram]} + \frac{1}{16} \text{[diagram]} + \frac{1}{12} \text{[diagram]} \\
 & + \frac{1}{4} \text{[diagram]} + \frac{1}{2} \text{[diagram]} + \frac{1}{2} \text{[diagram]} \\
 & + \frac{1}{8} \text{[diagram]} + \frac{1}{4} \text{[diagram]} + \frac{1}{4} \text{[diagram]} + \frac{1}{8} \text{[diagram]} \\
 & + \frac{1}{8} \text{[diagram]} + \frac{1}{4} \text{[diagram]} + \frac{1}{4} \text{[diagram]} \\
 & + \frac{1}{8} \text{[diagram]} + \frac{1}{2} \text{[diagram]} + \frac{1}{8} \text{[diagram]} + \frac{1}{4} \text{[diagram]} \\
 & + \frac{1}{16} \text{[diagram]} + \frac{1}{8} \text{[diagram]} + \frac{1}{4} \text{[diagram]} \\
 & + \frac{1}{2} \text{[diagram]} + \frac{1}{16} \text{[diagram]} + \frac{1}{12} \text{[diagram]} + \frac{1}{16} \text{[diagram]} \\
 & + \frac{1}{32} \text{[diagram]} + \frac{1}{16} \text{[diagram]} + \frac{1}{8} \text{[diagram]} \\
 & + \frac{1}{4} \text{[diagram]} + \frac{1}{8} \text{[diagram]} + \frac{1}{4} \text{[diagram]} + \frac{1}{8} \text{[diagram]} \\
 & + \frac{1}{12} \text{[diagram]} + \frac{1}{128} \text{[diagram]} + \frac{1}{32} \text{[diagram]}
 \end{aligned}$$

} φ^3 $SU(N)$

QCD skeletons:

$$\begin{aligned}
 \Phi_2 = & \frac{1}{8} \text{[diagram]} + \frac{1}{12} \text{[diagram]} - \frac{1}{2} \text{[diagram]} \\
 \Phi_3 = & \frac{1}{24} \text{[diagram]} - \frac{1}{3} \text{[diagram]} - \frac{1}{4} \text{[diagram]} + \frac{1}{8} \text{[diagram]} + \frac{1}{48} \text{[diagram]} \\
 \Phi_4 = & \frac{1}{72} \text{[diagram]} - \frac{1}{4} \text{[diagram]} - \frac{1}{6} \text{[diagram]} \\
 & + \frac{1}{12} \text{[diagram]} - \frac{1}{2} \text{[diagram]} - \frac{1}{2} \text{[diagram]} \\
 & - 1 \text{[diagram]} - \frac{1}{3} \text{[diagram]} + \frac{1}{6} \text{[diagram]} + \frac{1}{6} \text{[diagram]}
 \end{aligned}$$

and ring diags:

$$\begin{aligned}
 (-F_{(\text{rings})})_3 = & \frac{1}{4} \text{[diagram]} - \frac{1}{2} \text{[diagram]} + \frac{1}{4} \text{[diagram]} \\
 (-F_{(\text{rings})})_4 = & \frac{1}{6} \text{[diagram]} + \frac{1}{2} \text{[diagram]} + \frac{1}{4} \text{[diagram]} \\
 & - \frac{1}{3} \text{[diagram]} - 1 \text{[diagram]} - \frac{1}{2} \text{[diagram]}
 \end{aligned}$$

$\lambda \varphi^4$

4d perturbation theory in g hits the infrared wall at order g^6 :

$$\frac{p}{p_{SB}} = 1 + c_1 g^2 + c_2 g^3 + c_3 g^4 \ln \frac{1}{g} + c_4 g^4 + c_5 g^5 + c_6 g^6 \ln \frac{1}{g} + c_7 g^6 + \dots$$

c_7 : numerically computable

$N_f = 0$:

Relevant distance and matching scales:

Λ = ultraviolet scale for f_E (theory at scale T)

Λ_E = infrared scale for f_E **AND** UV scale for f_M

Λ_M = IR scale for f_M **AND** UV scale for f_G

Note:

- Matching scales Λ_E, Λ_M cancel
- No IR scale for f_G
- Big technical problem: dim reg in MSbar has UV scale = IR scale!

Braaten-Nieto decomposition (omit $\lambda_E \sim g^4$): PRD53(96)3421

$$\begin{aligned}
 F/T &= f_E + f_M + f_G \\
 &= f_E(\Lambda; T, g(\Lambda); \Lambda_E) + \\
 &\quad + f_M(\Lambda_E; m_E(\Lambda, g^2(\Lambda), \Lambda_E), g_E^2(\Lambda, g^2(\Lambda)); \Lambda_M) + \\
 &\quad + f_G(\Lambda_M; g_M^2(\frac{g_E^2}{m_E})) \\
 &= T^3 [1 + g^2(\Lambda) + (2\beta_0 \log \frac{\Lambda}{T} + \log \frac{T}{\Lambda_E}) g^4(\Lambda) + \\
 &\quad + (\dots + 2\beta_1 \log \frac{\Lambda}{T} + a \log \frac{T}{\Lambda_E}) g^6(\Lambda) + \dots] \\
 &\quad + \Lambda_E^3 + \Lambda_E^2 g_E^2 + \Lambda_E m_E^2 + \Lambda_E g_E^4 + \\
 &\quad + m_E^3 + \log \frac{\Lambda_E}{m_E} \cdot m_E^2 g_E^2 + m_E g_E^4 + \\
 &\quad + (a \log \frac{\Lambda_E}{m_E} + b \log \frac{m_E}{\Lambda_M}) g_E^6 \\
 &\quad + \Lambda_M^3 + \Lambda_M^2 g_M^2 + \Lambda_M g_M^4 + b \log \frac{\Lambda_M}{g_M^2} \cdot g_M^6
 \end{aligned}$$

$m_E \sim gT$

E

M

G

We need a and $b = 4\text{loop UV divergences of } f_M, f_G$.

find: $b \gg a$!

3d effective theory for f_M

is a 3d SU(3) gauge + adjoint Higgs theory:

$$N_f = 0$$

$$\begin{aligned}
 \exp[-V f_M(T/\Lambda_{\overline{\text{MS}}})] &= \int \mathcal{D}A_i^a \mathcal{D}A_0^a \exp\{- \int d^3x \times \\
 &\quad [\frac{1}{4} F_{ij}^a F_{ij}^a + \frac{1}{2} (D_i A_0)^a (D_i A_0)^a + \\
 &\quad + \underbrace{\frac{1}{16\pi^2} (22 \log \frac{5.371T}{\Lambda_{\overline{\text{MS}}} + 9)}_{\equiv y/2 \sim 1/g^2}} A_0^a A_0^a + \\
 &\quad + \underbrace{\frac{3}{44 \log(5.371T/\Lambda_{\overline{\text{MS}}})}}_{\equiv x/4} (A_0^a A_0^a)^2 + \dots\}
 \end{aligned}$$

$$A_i, A_0, x, \text{ dimensionless, } D_i = \partial_i + g A_i$$

The coefficients are determined in next-to-leading-order optimised perturbation theory.

Challenging problem: compute them to NNLO!

Note: $f_M(x, y)$ is defined for any x, y ; 4d physics or $f_M(T/\Lambda_{\overline{\text{MS}}})$ is on the curve $y = 3/(8\pi^2 x)(1 + 3x/2 + \mathcal{O}(x^2))$.

The $g^6 \log g$ terms are

$$\frac{f}{g^6} = \underbrace{a \log \frac{T}{\Lambda_E}}_{4d \text{ theory}} + \underbrace{a \log \frac{\Lambda_E}{m_E} + b \log \frac{m_E}{\Lambda_M} + b \log \frac{\Lambda_M}{g_M^2}}_{3d \text{ theory}}$$

Adding:

$$\frac{f}{g^6} = a \log \frac{T}{m_E} + b \log \frac{m_E}{g_M^2} = (a + b) \log \frac{1}{g}$$

We will discuss 3d theories in MSbar or lattice regularisation with ONE regularisation scale, g_E^2 or $1/a$ (relating the two schemes correctly is crucial). In the 3d sector the log term is ($\Lambda_E \sim \Lambda_M \sim g_E^2$)

$$a \log \frac{g_E^2}{m_E} + b \log \frac{m_E}{g_E^2} = (-a + b) \log \frac{1}{g}$$

The (colossal) 4-loop perturbative computation of a, b is under way.

To get b you must find the UV log div of 3d SU(3) gauge theory. In msbar the result is ZERO since no scale whatsoever in the problem: UV + IR = 0. The IR singularities have to be shielded by a gluon mass, say.

In the 3d sector

$$\begin{aligned} (f_M + f_G)/T^3 = & \\ g^3 + g^4 \log \frac{1}{g} + g^5 + & \leftarrow \text{known} \\ + (-a + b)g^6 \log \frac{1}{g} + & \leftarrow \text{find numerically} \\ + cg^6] & \leftarrow \text{numerically small} \end{aligned}$$

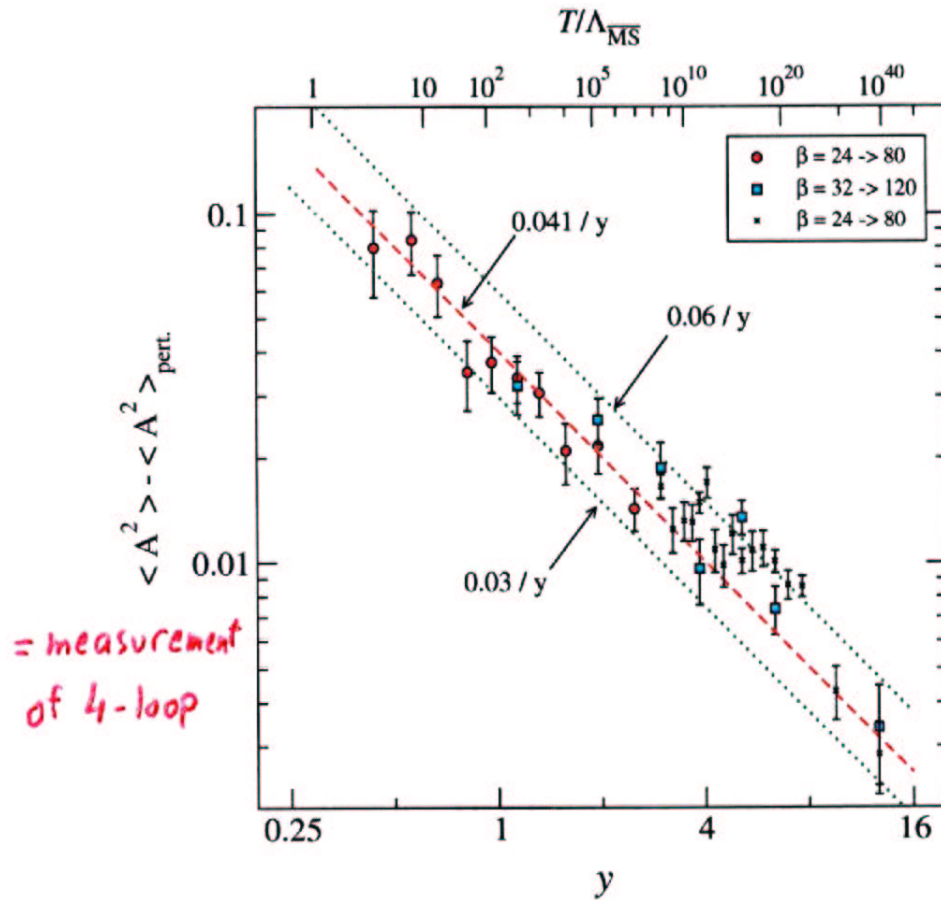

Determine $-a + b$ numerically by

$$\frac{\partial((f_M + f_G)/g^6)}{\partial(1/g^2)} = \frac{1}{g} + \log \frac{1}{g} + 1 + g + (-a + b)\frac{g^2}{2} \sim \langle A_0^2 \rangle$$

$$e^{-f} = \int \mathcal{D}A_0 e^{-yA_0^2 + \dots}$$

So measure on the lattice $\langle A_0^2 \rangle$, relate lattice and MSbar schemes, take the large V small a (continuum) limits, subtract the known 1+2+3-loop perturbative part and find the $g^2 \sim 1/y \sim 1/\log(T/\Lambda_{\overline{\text{MS}}})$ dependence:

Result ($y \sim 1/g^2 \sim \log(T/\Lambda_{\overline{MS}})$); after $6 \cdot 10^{15}$ flops:

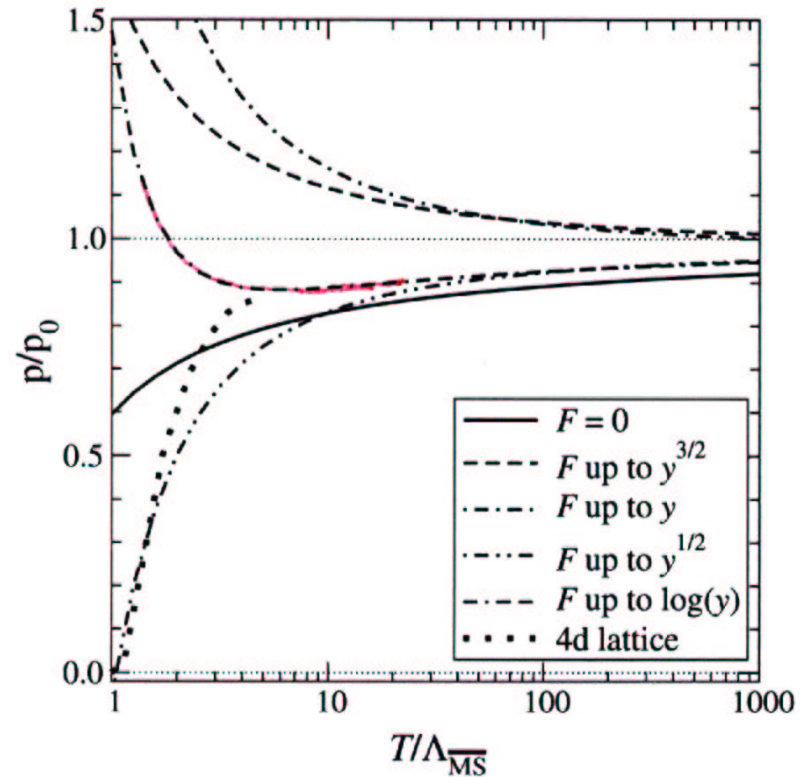

The Jan 17 15:06:07 2002

$$\Rightarrow \frac{d_A C_A^3}{2(4\pi)^4} (-a + b) = 0.041(2) \rightarrow -a + b = 9.5$$

$$d_A = 8, C_A = 3$$

Note that 0.04/ y saturates data over all y !

The physical pressure $p/p_{SB} = 1 + \dots + (a + b)g^6 \log g + cg^6$ and we know $-a + b$. Let's assume b dominates and see what we get:

Excellent connection to 4d lattice data at about $T = 5T_c$!

Note that there are no further terms; everything is in the numerics.

Suggests that a (UV log of 3d) and c (the entirely nonperturbative constant) are small!

Conclusions

- We are now in hot QCD progressing like in jet physics or DIS: there is an “infinite” perturbative series (LO,NLO,NNLO,..) series leading to logarithmic scale dependence and something entirely nonperturbative (pdf at some scale, the g^6 constant)
- At the 4loop NNNLO level in hot QCD there are two log-constants a, b ; the combination $-a + b$ has been numerically determined
- The analytic computation is under way: the 4loop computation of $g^4\lambda, g^2\lambda^2, \lambda^3$ terms is done
- A good connection to 4d lattice data at $T = T_c$ using just b (the UV divergence of 3d SU(3) gauge theory) suggests that the other constants are numerically small
