

The search for young massive clusters in our Galaxy

Margaret Hanson &
Bogdan Popescu

The background of the slide is a deep-space photograph of the Antennae Galaxy (NGC 4038/4039). It shows two galaxies in the process of colliding, with long, curved tails of gas and dust extending from their cores. The galaxy cores are bright yellow and orange, while the surrounding interstellar medium is filled with numerous blue and white stars, indicating active star formation triggered by the collision.

High mass clusters are being formed today

HST ‘discovered’
YOUNG star
clusters with the
mass of Galactic
globular clusters, as
seen in the colliding
Antennae Galaxy.

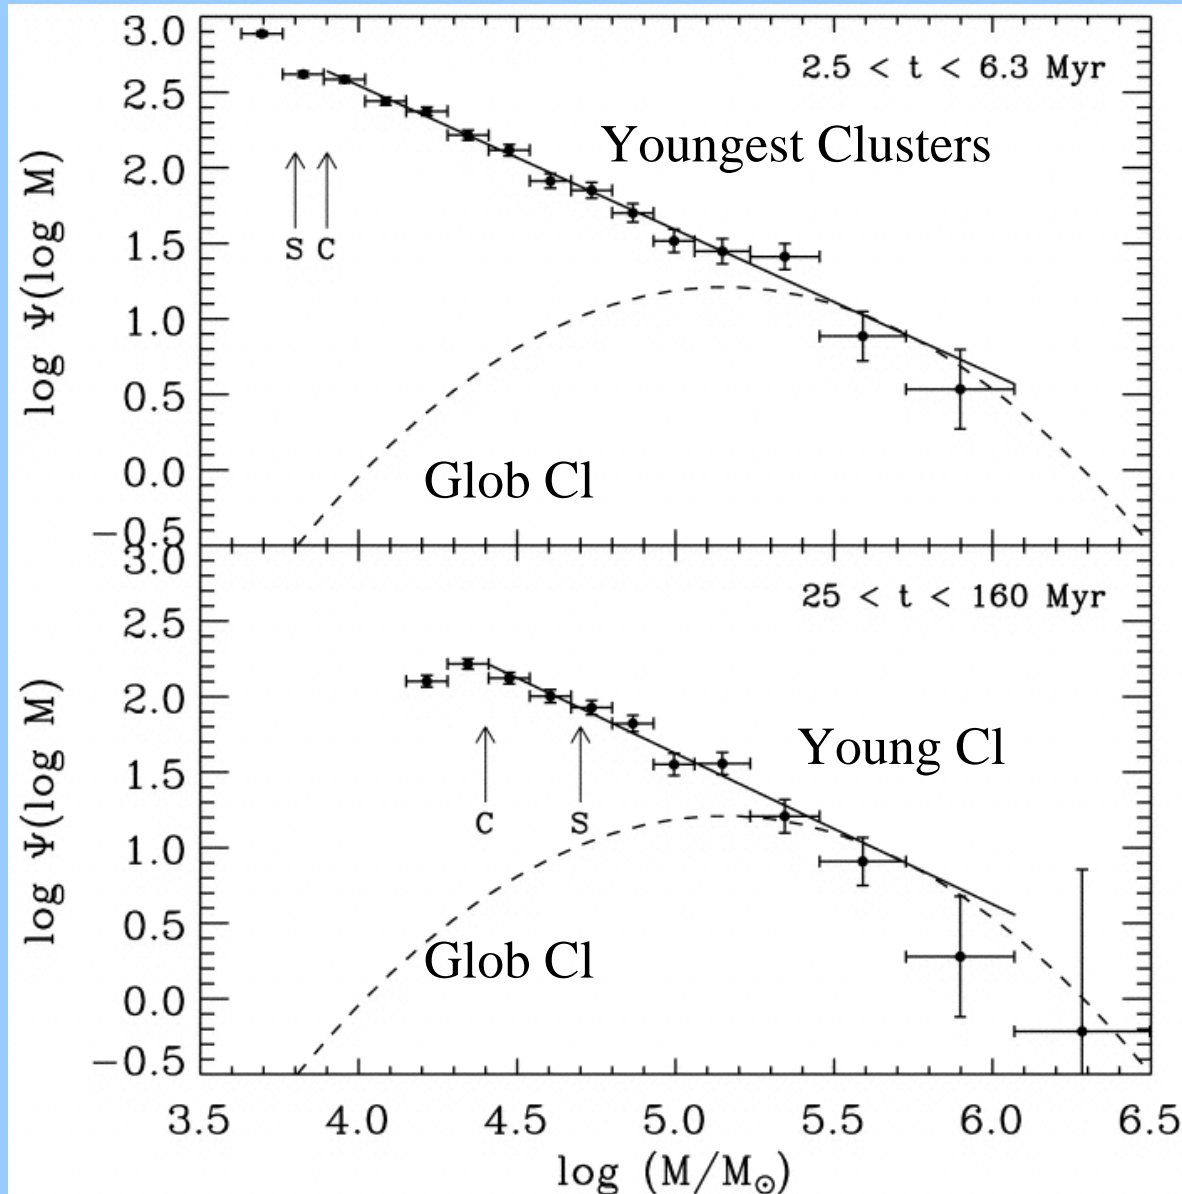

This was unlike
any known star formation
currently in the Milky Way

Extragalactic Young Massive Clusters

Zhang & Fall (1999)

Found clusters with the masses of Galactic globulars, but only tens of millions years old.

The number of clusters follows a power law, slope -2, over the mass range
 $10^4 < M < 10^6$

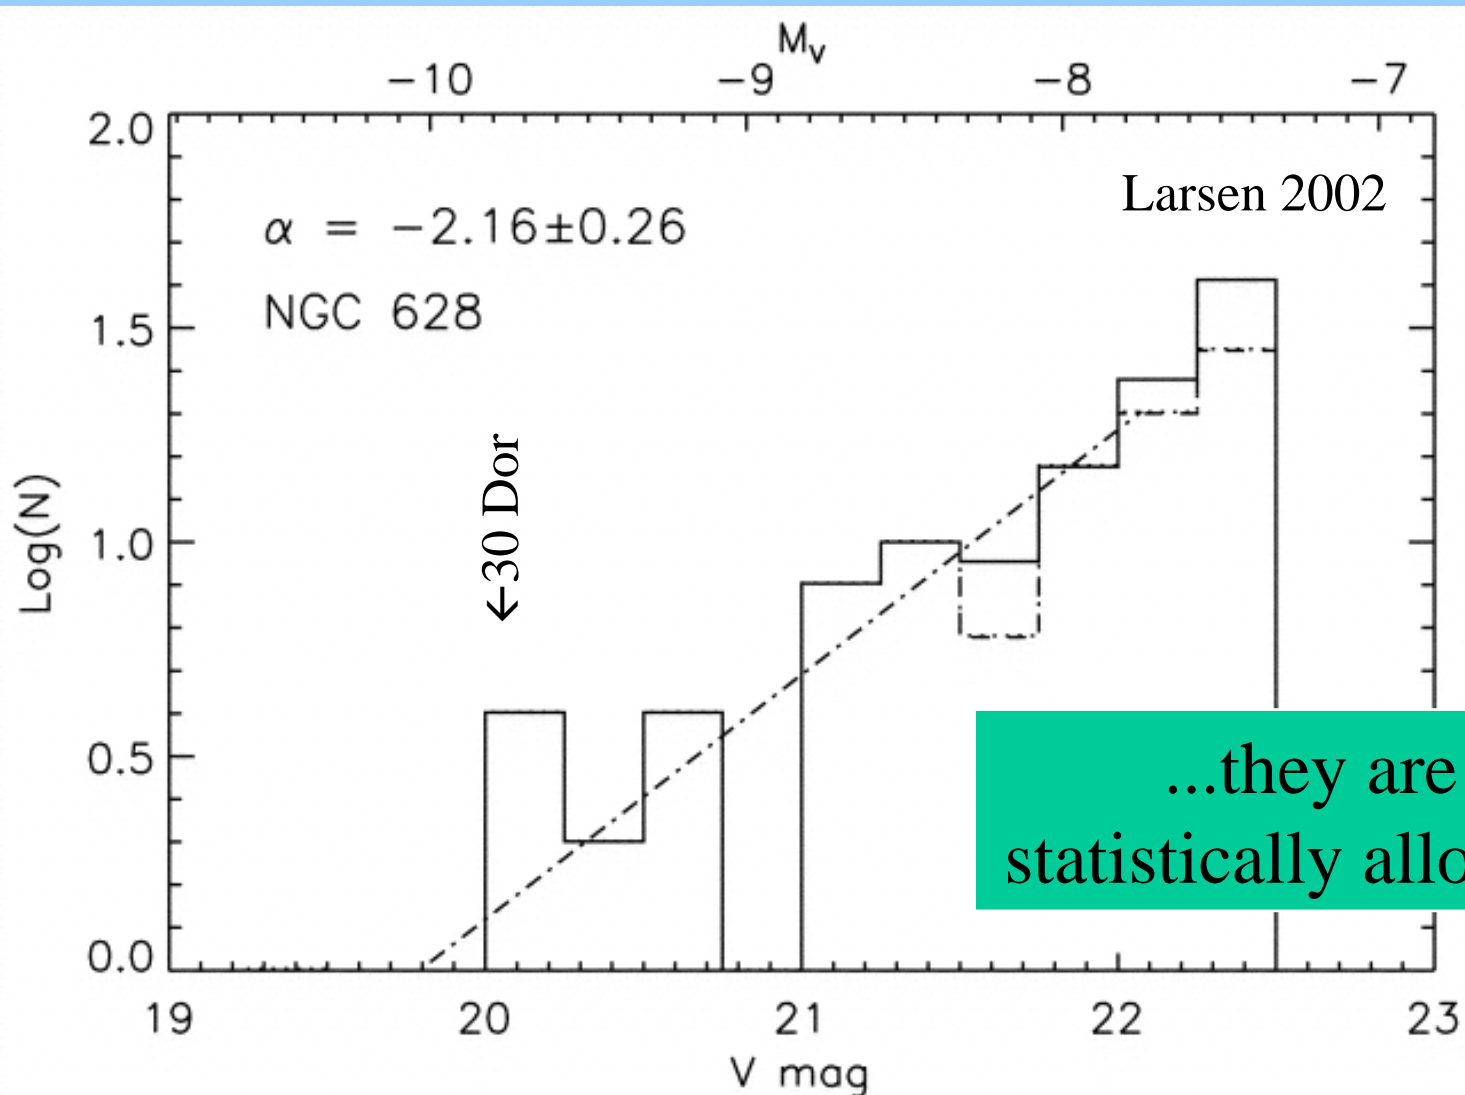

But don't you need mergers to make very massive young clusters?

NGC 628

No! Isolated spiral galaxies will show massive young clusters. Provided..

...they are statistically allowed.

Does such a power law apply to clusters in the Milky Way?

The cluster luminosity function:

- Most massive: few $\times 10^3 M_{\odot}$
- Survey's are complete to 1-2 kpc
- Number of clusters as fcn of M_V , is a power law, slope -2
- The present day Globular Clusters follow a similar power law (see Harris & Pudritz 1994)

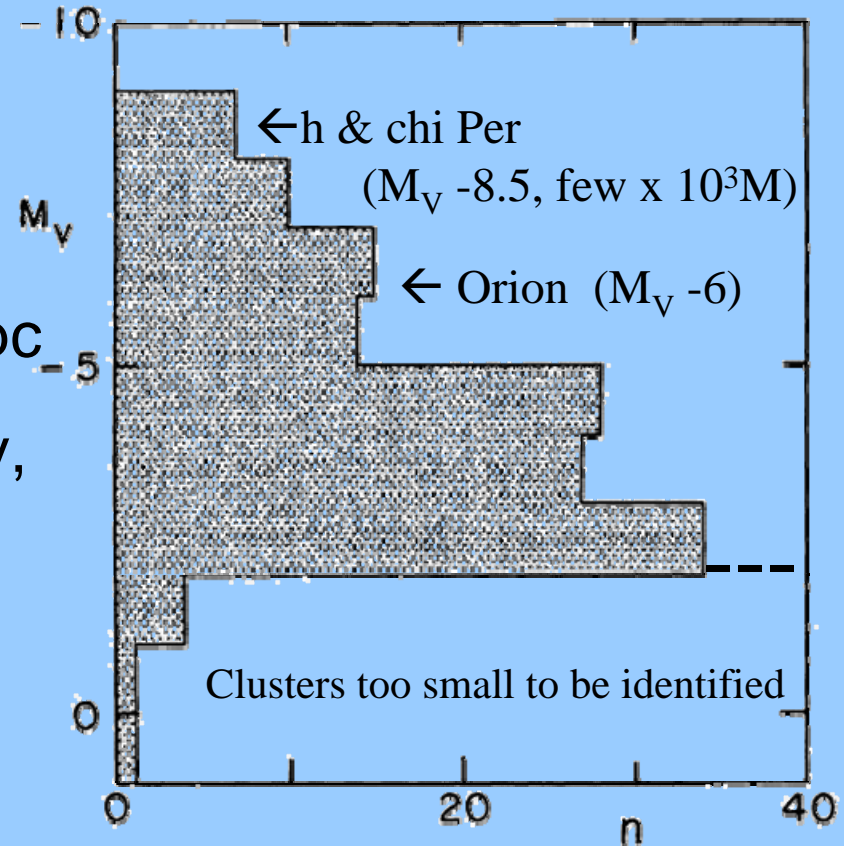

FIG. 1. Luminosity distribution of clusters contained in the catalog of Sagar *et al.* The paucity of clusters fainter than $M_V = -2$ is probably due to selection effects.

van den Bergh & Lafontaine (1984)

Optical stellar surveys are complete for less than 10% of the inner disk.

Well studied region of our Galaxy.

What if we could see our whole Galaxy?

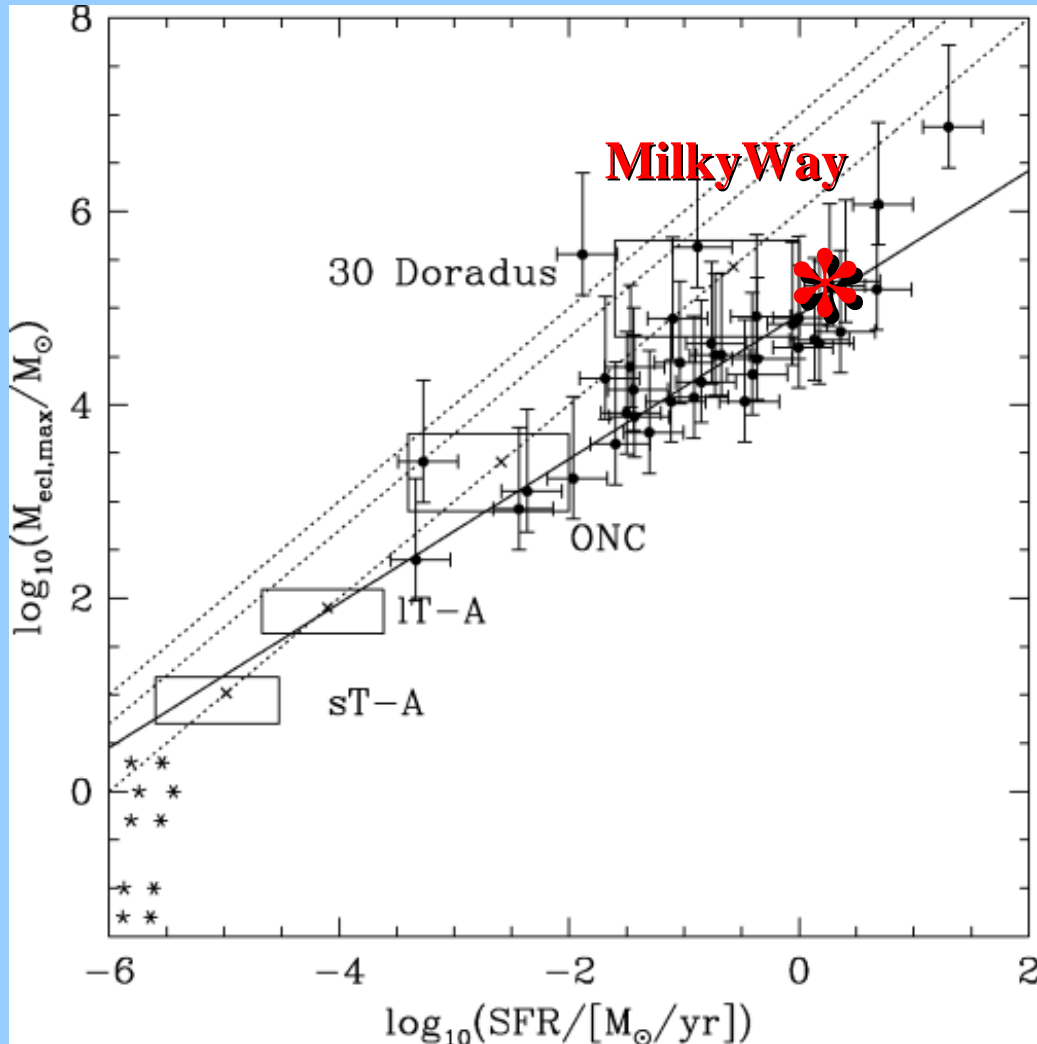

The locally derived, luminosity function of Milky Way star clusters *predicts* (vdB & Lf 1984):

- **100** clusters will have $M_V = -11$ ($M=10^4$ Msun)
- A few clusters will have $M_V < -12$ ($M \geq 10^5$ Msun)

van den Bergh & Lafontaine 1984:

“It is hard to believe the Galaxy contains so many undiscovered super luminous open clusters. This suggests that the luminosity function of galactic clusters starts to fall below the extrapolation in the range $-11 < M_V < -8$.”

If we are a normal galaxy, the Milky Way will contain 'Super Star Clusters'.

External galaxies show a correlation between the SFR rate and the most massive **young** cluster found.

If the Milky Way is like other galaxies, the most massive clusters predicted to form are $M \sim 10^5 - 10^6 M_{\text{sun}}$

Weidner *et. al* 2004

How do we find these massive clusters?

Numerous cluster searches based on 2MASS exist:
Bica, Dutra, et al. set of surveys (2001, 2003, etc)
Froebrich et al. (2007) found >1000 new IR Clusters.

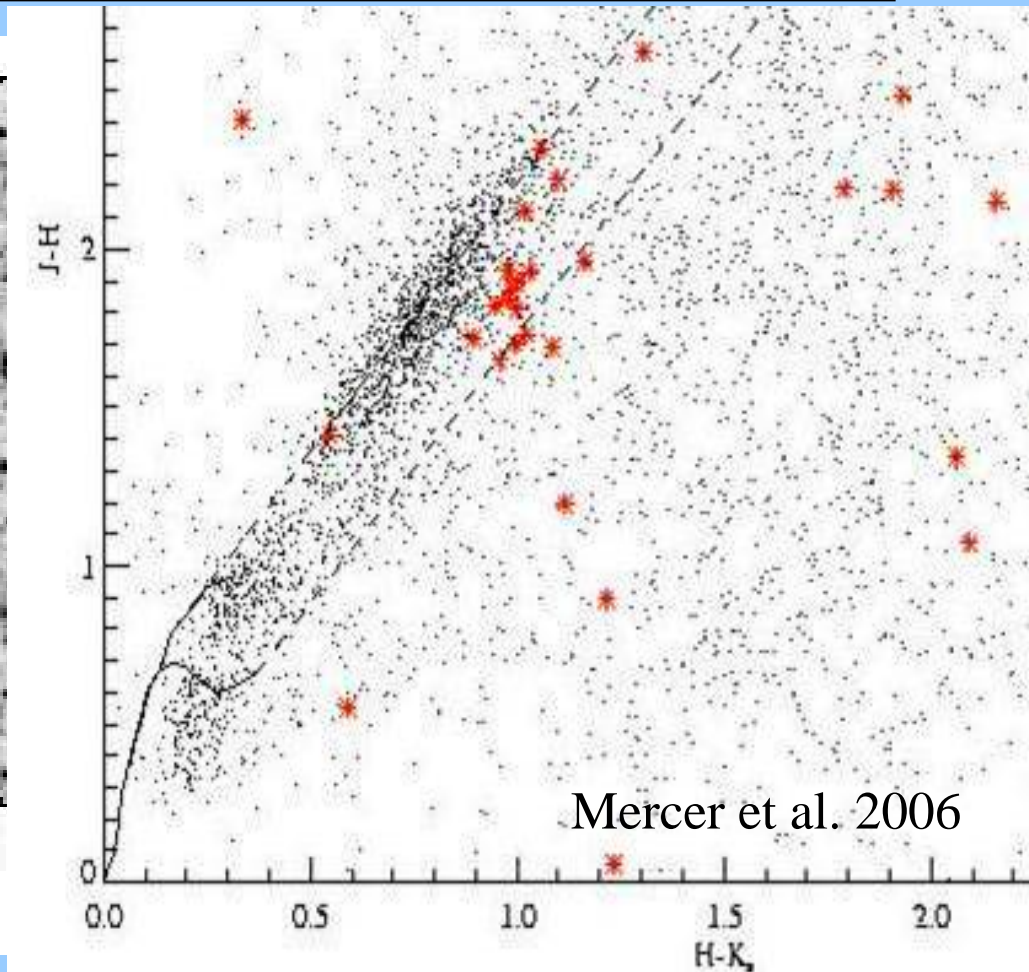

Our search uses GLIMPSE:

- GLIMPSE: completed in 2005, uses the Spitzer Space Telescope
- Four bands (3, 4.5, 6, 8 microns)
- Covers inner Galactic disk:
longitude = $|65^\circ|$, latitude = $|1^\circ|$
- Probes deeper than 2MASS
- Mercer et al. (2005) have identified almost 100 new clusters.

Young, 'Blue' clusters found with GLIMPSE

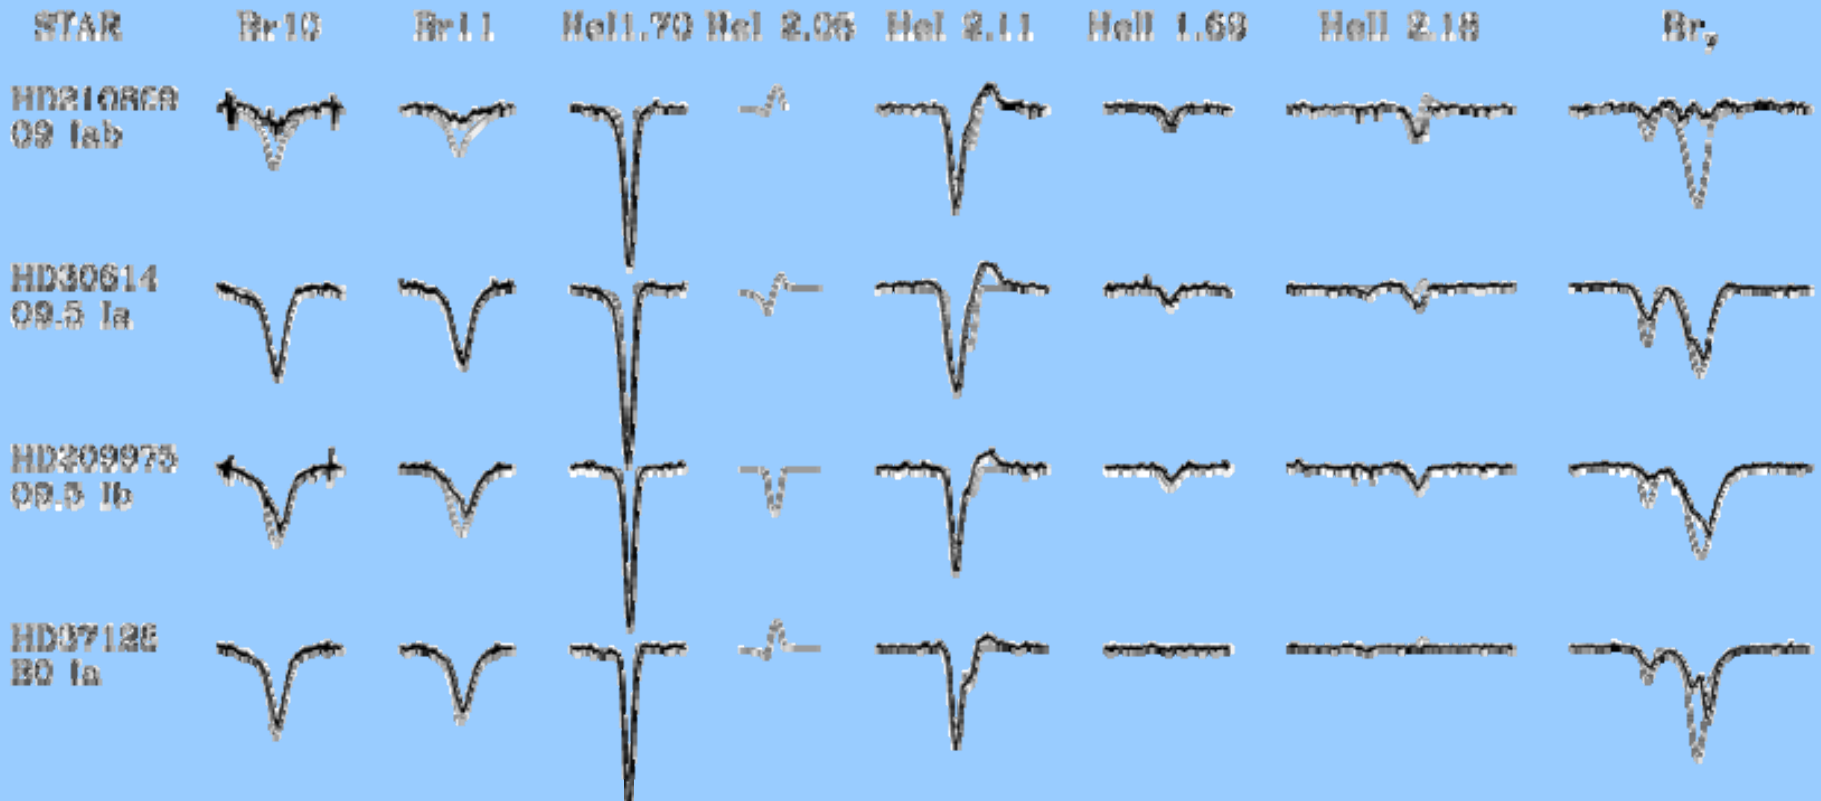

4 micron image α (J2000)

Small concentration of stars (*) show similar 'blue color' indicating a young, luminous cluster. $A_v=15$

Spectra of Hot Stars at 2 microns

We (Cincinnati/Munich) have a sophisticated atmospheric code that provides quantitative spectral analysis of hot stars *using near-infrared spectra alone*.

Westerlund 1, $M_v = -11$ (-12?)

$M \sim 10^5$ Suns (Clark et al. 2005)

$A_v = 11.5$, Distance = 4-5 kpc

JHK (1-2) micron image

Search selection biases are not understood

Might there be a high mass cut off among massive clusters, like has been proposed with high mass stars?

Gieles et al. (2006) on the Milky Way:

“Assuming the number density of clusters is constant out to $Wd\ 1$ (4.5 kpc).. We would expect at least one cluster above $10^6\ Mo.$..it is unlikely that a 10 times more massive object would not have been found yet within 4.5 kpc of the Sun. $Wd1$ is a reasonable upper limit [for the Milky Way].”

Unfortunately, the selection effects of current search methods are not well enough constrained to be sure.

Our Cluster Simulations demonstrate Biases

Westerlund 1 Simulation:

Mass = 10^5 Msun

Extinction: $A_V = 11$

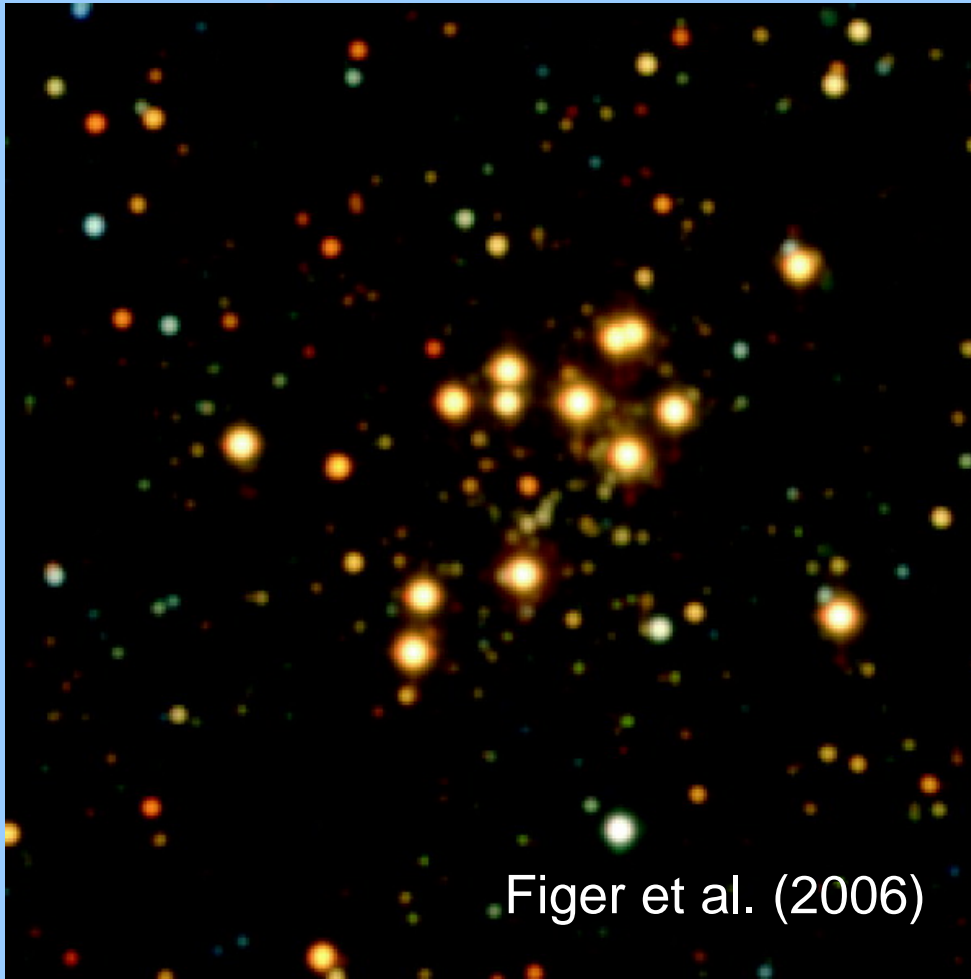

With mass segregation

Log(T) = 6.0 to 8.0 yr

With significant extinction, NIR is clearly required, but NIR searches are much more *age sensitive* than the optical.

Popescu & Hanson 2007

What will NIR searches uncover?

Found with 2MASS
(CL 122 Dutra et al. 2003)

Cited cluster properties:
14 RSG, 1 YSG, 10^4 - $10^5 M_{\odot}$
Few $\times 10^6$ yrs, ~ 5 kpc, $A_V=30$

Calibrating our simulations to known clusters

NGC 3603, J-Band Image

Stolte et al. (2004): 2×10^6 yrs, $7 \times 10^3 M_{\odot}$, $A_v=4.5$, 6 kpc

Future Research Goals

- Continue with near-infrared observations to uncover and characterize the massive clusters of the inner Milky Way.
- Simulate the Milky Way plane with massive clusters and use current NIR cluster search methods to estimate the number of massive clusters missed as fcn of mass, age, distance, A_v , cluster density, etc.
- Characterize resolved Local Group SSCs, compare with Starburst99/GALAXEV and strengthen models for distant unresolved SSC in other galaxies.

Input : Mass of the cluster (in solar units)

generator

n_distribution

writeindex

index_trek

trek

Compute the mass distribution (using Kroupé IMF).

Read the isochrones files from the Geneva Database.
Compute the photometric quantities for all the stars in the distribution and for all ages in the isochrones.

Input : King Model parameters (r_t , r_c)

random_king

Computes the King Model distribution.

Input : A_V , R_V

ccm_extinction

Computes CCM extinction curves.

Input : distance (pc)

Optional input : anisotropy parameters for King Model, rescaling parameters for multiple King clusters, mass segregation parameters, different values for extinction

Additional input : FOV, image size

star_sky

Computes positions and magnitudes (UBVRIJHK) for all stars and all ages ($\log(T)=3.0..10.2$).
Writes files for HR diagrams, color-magnitude diagrams, input files for SkyMaker (to generate FITS images).

Rescaling for multiple clusters (like H & Chi Persei)
